Abstract

We investigate the optimal performance of dense sensor networks by studying the joint source-channel coding problem. The overall goal of the sensor network is to take measurements from an underlying random process, code and transmit those measurement samples to a collector node in a cooperative multiple access channel with potential feedback, and reconstruct the entire random process at the collector node. We provide lower and upper bounds for the minimum achievable expected distortion when the underlying random process is Gaussian. When the Gaussian random process satisfies some general conditions, we evaluate the lower and upper bounds explicitly, and show that they are of the same order for a wide range of power constraints. Thus, for these random processes, under these power constraints, we express the minimum achievable expected distortion as a function of the power constraint. Further, we show that the achievability scheme that achieves the lower bound on the distortion is a separation-based scheme that is composed of multi-terminal rate-distortion coding and amplify-and-forward channel coding. Therefore, we conclude that separation is order-optimal for the dense Gaussian sensor network scenario under consideration, when the underlying random process satisfies some general conditions.

1 Introduction

With the recent advances in the hardware technology, small cheap nodes with sensing, computing and communication capabilities have become available. In practical applications, it is possible to deploy a large number of these nodes to sense the environment. In this paper, we investigate the optimal performance of a dense sensor network by studying the joint source-channel coding problem. The sensor network is composed of N sensors, where N is very large, and a single collector node. Each sensor node has the capability of taking noiseless samples from the underlying random process, and is equipped with one transmit and one receive antenna to transmit and receive signals. The overall goal of the sensor network is to take measurements from an underlying random process $S(t)$, $0 \leq t \leq T_0$, code and transmit those measured samples to a collector node, and reconstruct the entire random process at the collector node, with as little distortion as possible; see Figure 1. Due to the small distances between the sensor nodes and the correlation in the measured data, the underlying sources are correlated, and due to the existence of receive antennas at the sensor nodes and a transmit antenna at the collector node, the communication channel is a Gaussian cooperative multiple access channel with potential feedback. We investigate the minimum achievable expected distortion and the corresponding achievability scheme when the underlying random process is Gaussian.

Following the seminal paper of Gupta and Kumar [3], which showed that multi-hop wireless ad-hoc networks, where users transmit independent data and utilize single-user coding, decoding and forwarding techniques, do not scale up, Scaglione and Servetto [4] investigated the scalability of the sensor networks. Sensor networks, where the observed data is correlated, may scale up for two reasons: first, the correlation among the sampled data increases with the increasing number of nodes and hence, the amount of information the network needs to carry does not increase as fast as in ad-hoc wireless networks; and second, correlated data facilitates cooperation, and may increase the information carrying capacity of the network. The goal of the sensor network in [4] was that each sensor reconstructs the data measured by all of the sensors using sensor broadcasting. In this paper, we focus on the case where the reconstruction is required only at the collector node. Also, in this paper, the task is not the reconstruction of the data the sensors measured, but the reconstruction of the underlying random process.

Gastpar and Vetterli [5] studied the case where the sensors observe a noisy version of a linear combination of L Gaussian random variables which all have the same variance, code and transmit those observations to a collector node, and the collector node reconstructs the L random variables. In [5], the expected distortion achieved by applying separation-based approaches was shown to be exponentially worse than the lower bound on the minimum achievable expected distortion. In this paper, we study the case where the data of interest at the collector node is not a finite number of random variables, but a random process,

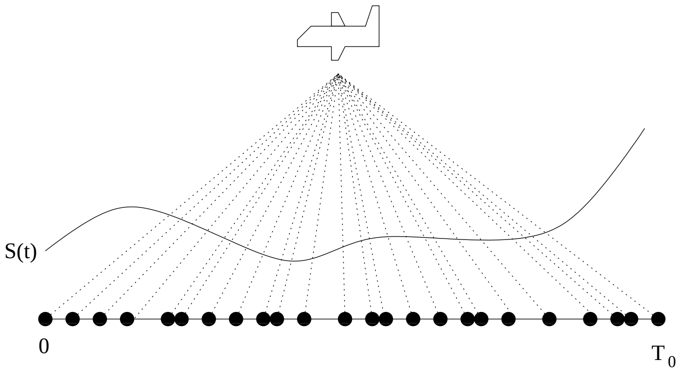

Figure 1: Sensor network.

which, using Karhunen-Loeve expansion, can be shown to be equivalent to a set of infinitely many random variables with varying variances. We assume that the sensors are able to take noiseless samples, but that each sensor observes only its own sample. Our upper bound on the minimum achievable distortion is also developed by using a separation-based approach, but it is shown to be of the same order as the lower bound, for a wide range of power constraints, for random processes that satisfy some general conditions.

El Gamal [6] studied the capacity of dense sensor networks and found that all spatially band-limited Gaussian processes can be estimated at the collector node, subject to any non-zero constraint on the mean squared distortion. In this paper, we study the minimum achievable expected distortion for space-limited, and thus, not band-limited, random processes, and we show that the minimum achievable expected distortion decreases to zero as the number of nodes increases, unless the power constraint is unusually small. Also, in [6], it is assumed that the channel gains between the nodes decrease with the distance between them, without enforcing any upper bounds. This implies that, when the sensors are placed very densely, the channel gains between nearby sensors become unboundedly large. This physically impossible situation arises because although the channel model used in [6] is valid only in the far field of the transmitter, it is used for all distances. Although we adopted this channel model in [1], we have changed the channel model to a more realistic one in this paper (and [2]), where we assume that the channel gains decrease with distance, however, they are lower and upper bounded. The difference in the channel models in [1] and here (and [2]), does not affect our conclusion, i.e., in both cases, we are able to find achievable schemes that achieve the lower bound on the distortion. However, it affects the achievability scheme itself; in [1] the achievability scheme is based on the basic idea of decode-and-forward as the channel model allows a significant number of nodes to be able to decode successfully the signal transmitted by a node, whereas the achievability scheme here (and [2]) is based on the basic idea of amplify-and-forward, where due to the lower and upper bounds on the channel gains a sufficient amount of beamforming effect is achieved through the amplify-and-forward scheme.

From an information theoretic point of view, our problem is a joint source-channel coding problem for lossy communication of correlated sources over a cooperative Gaussian multiple access channel with potential feedback. The simpler problem of lossless reconstruction of correlated sources over a multiple access channel without cooperation or feedback still remains open [7–10]. Therefore, a direct and closed-form expression for the distortion seems unlikely to be obtained, and consequently, we resort to developing lower and upper bounds. We first provide lower and upper bounds for the minimum achievable expected distortion for arbitrary Gaussian random processes whose Karhunen-Loeve expansion exists. Then, we focus on the case where the Gaussian random process also satisfies some general conditions. For these random processes, we evaluate the lower and upper bounds explicitly, and show that they are of the same order, for a wide range of power constraints. Thus, for these random processes, under a wide range of power constraints, we determine the order-optimal achievability scheme, and identify the minimum achievable expected distortion. Our achievability scheme is separation-based: each sensor first performs multi-terminal source coding [11], then, performs channel coding, and utilizes the cooperative nature of the wireless medium through the amplify-and-forward scheme [12]. In multi-user information theory, generally speaking, the separation principle does not hold. However, in our case, we have found a scheme which is separation based, and is order-optimal.

2 System Model

The collector node wishes to reconstruct a random process $S(t)$, for $0 \leq t \leq T_0$, where t denotes the spatial position; $S(t)$ is assumed to be Gaussian with zero-mean and a continuous autocorrelation function $K(t,s)$. The N sensor nodes are placed at positions $0 = t_1 \leq t_2 \leq \cdots \leq t_N = T_0$, and observe samples $\mathbf{S}_N = (S(t_1), S(t_2), \cdots, S(t_N))$. For simplicity and to avoid irregular cases, we assume that the sensors are equally spaced, i.e.,

$$t_i = \frac{i-1}{N-1} T_0, \qquad i = 1, 2, \cdots, N \tag{1}$$

The distortion measure is the squared error,

$$d(s(t), \hat{s}(t)) = \frac{1}{T_0} \int_0^{T_0} (s(t) - \hat{s}(t))^2 dt \tag{2}$$

Each sensor node and the collector node, denoted as node 0, is equipped with one transmit and one receive antenna. To simplify the presentation, from now until Section 7, we will assume that the collector node does not use its transmit antenna, and thus, there is no feedback in the system. We will allow the collector node to use its transmit antenna and provide feedback to the sensor nodes in Section 7, and show that the results of the previous sections remain unchanged. At any time instant, let X_i denote the signal transmitted by node i, and Y_j denote the signal received at node j. Let h_{ij} denote the channel gain from node i to node j. Then, the received signal at node j can be written as,

$$Y_j = \sum_{i=1, i \neq j}^{N} h_{ij} X_i + Z_j, \qquad j = 0, 1, 2, \cdots, N \tag{3}$$

where $\{Z_j\}_{j=0}^{N}$ is a vector of $N+1$ independent and identically distributed, zero-mean, unit-variance Gaussian random variables. Therefore, the channel model of the network is such that all nodes hear a linear combination of the signals transmitted by all other nodes at that time instant. We assume that the channel gain h_{ij} is bounded, i.e.,

$$\bar{h}_l \leq h_{ij} \leq \bar{h}_u, \qquad i = 1, \cdots, N, \quad j = 0, 1, \cdots, N \tag{4}$$

where $\bar{h}_u$ and $\bar{h}_l$ are positive constants independent of N. This model is very general and should be satisfied very easily. By the conservation of energy, $h_{ij}^2 \leq 1$, and since all nodes are within finite distances of each other, the channel gains should be lower bounded as well.

We assume that all sensors have the same individual power constraint $P(N)/N$, where $P(N)$, which we will call the total power, is the sum of the individual power constraints, and it is a function of N. The two most interesting cases for $P(N)$ are $P(N) = NP_{\text{ind}}$ where each sensor has its individual power constraint P_{ind}, and $P(N) = P_{\text{tot}}$ where the total power is a constant P_{tot} and does not depend on the number of sensors. In the latter case, when more and more sensor nodes are deployed, the individual power of each sensor node decreases as P_{tot}/N. Our goal is to determine the scheme that achieves the minimum achievable expected distortion D^N at the collector node for a given total power $P(N)$, and also to determine the rate at which this distortion goes to zero as a function of the number of sensor nodes and the total power.

Next, we give a more precise definition of our problem. Each sensor node observes a sample of a sequence of spatial random processes $\{S^{(l)}(t)\}_{l=1}^{n}$ i.i.d. in time, where index l denotes time, t denotes the spatial position, and n is the block length of the sequence of random processes, and also the delay parameter. For now, we assume that n channel uses are allowed for n realizations of the random process; the case where we allow the number of channel uses and the number of observations to differ will be treated in Section 7. At time instant m, sensor node j transmits

$$X_j(m) = F_j^{(m)}(\{S^{(l)}(t_j)\}_{l=1}^{n}, \{Y_j^{(l)}\}_{l=1}^{m-1}), \quad m = 1, 2, \cdots, n, \quad j = 1, 2, \cdots, N \tag{5}$$

i.e., it transmits a signal that is a function of its observations of the entire block of random process samples and also the signal it received before time m. We are interested in the performance in the information-theoretic sense and hence, we allow the delay n to be arbitrarily large. By the assumption of identical individual power constraints, we have

$$\frac{1}{n}\sum_{m=1}^{n} E[X_j^2(m)] \leq \frac{P(N)}{N}, \quad j = 1, 2, \cdots, N \tag{6}$$

The collector node reconstructs the random process as

$$\{\hat{S}^{(l)}(t), t \in [0, T_0]\}_{l=1}^{n} = G(Y_0^{(1)}, Y_0^{(2)}, \cdots, Y_0^{(n)}) \tag{7}$$

For fixed encoding functions of the nodes $\{F_j^{(m)}\}_{m=1,j=1}^{m=n,j=N}$ and the decoding function of the collector node G, the achieved expected distortion is

$$\frac{1}{n}\sum_{l=1}^{n} E\left[d\left(S^{(l)}(t), \hat{S}^{(l)}(t)\right)\right] \tag{8}$$

and we are interested in the smallest achievable expected distortion over all encoding and decoding functions where n is allowed to be arbitrarily large.

In this paper, our purpose is to understand the behavior of the minimum achievable expected distortion when the number of sensor nodes is very large. We introduce the big-O and big-Θ notations. We say that f is $\mathrm{O}(g)$, if there exist constants c and k, such that $|f(N)| \leq c|g(N)|$ for all $N > k$; we say that f is $\Theta(g)$, if there exist constants c_1, c_2 and k such that $c_1|g(N)| \leq |f(N)| \leq c_2|g(N)|$ for all $N > k$. All logarithms are defined with respect to base e, and $\lfloor x \rfloor$ denotes the largest integer smaller than or equal to x.

3 A Class of Gaussian Random Processes

For a Gaussian random process $S(t)$ with a continuous autocorrelation function, we perform the Karhunen-Loeve expansion [13],

$$S(t) = \sum_{k=0}^{\infty} S_k \phi_k(t) \tag{9}$$

to obtain the ordered eigenvalues $\{\lambda_k\}_{k=0}^{\infty}$, and the corresponding eigenfunctions $\{\phi_k(t), t \in [0, T_0]\}_{k=0}^{\infty}$.

Let $\mathcal{A}$ be the set of Gaussian random processes on $[0, T_0]$ with continuous autocorrelation functions, that satisfy the following conditions:

1. There exist nonnegative constant d and nonnegative integers c_l, c_u, $K_0 \geq c_u + 1$ and

two sequences of numbers $\{\lambda'_k\}_{k=0}^{\infty}$ and $\{\lambda''_k\}_{k=0}^{\infty}$ defined as

$$\lambda'_k = \begin{cases} \lambda_k, & k \le K_0 \\ \frac{d}{(k+c_l)^x}, & k > K_0 \end{cases} \tag{10}$$

and

$$\lambda''_k = \begin{cases} \lambda_k, & k \le K_0 \\ \frac{d}{(k-c_u)^x}, & k > K_0 \end{cases} \tag{11}$$

for some constant $x > 1$, such that

$$\lambda'_k \le \lambda_k \le \lambda''_k \tag{12}$$

The condition that $x > 1$ is without loss of generality, because for all continuous autocorrelations, the eigenvalues decrease faster than k^{-1}.

2. In addition to continuity, $K(t,s)$ satisfies the Lipschitz condition of order $1/2 < \alpha \le 1$, i.e., there exists a constant $B > 0$ such that

$$|K(t_1,s_1) - K(t_2,s_2)| \le B\left(\sqrt{(t_1-t_2)^2 + (s_1-s_2)^2}\right)^{\alpha} \tag{13}$$

for all $t_1, s_1, t_2, s_2 \in [0, T_0]$.

3. For $k = 0, 1, \cdots$, the function $\phi_k(s)$ and the function $K(t,s)\phi_k(s)$ as a function of s satisfy the following condition: there exist positive constants B_1, B_2, B_3, B_4, $\beta \le 1$, $\gamma \le 1$, and nonnegative constant τ, independent of k, such that

$$|\phi_k(s_1) - \phi_k(s_2)| \le B_3(k+B_4)^{\tau}|s_1 - s_2|^{\gamma} \tag{14}$$

and

$$|K(t,s_1)\phi_k(s_1) - K(t,s_2)\phi_k(s_2)| \le B_2(k+B_1)^{\tau}|s_1 - s_2|^{\beta} \tag{15}$$

for all $t, s_1, s_2 \in [0, T_0]$.

The reasons why these conditions are needed for the explicit evaluation of the lower and upper bounds on the minimum achievable expected distortion will be clear from the proofs. Here, we provide some intuition as to why they are needed. Condition 1 states that we consider random processes that have eigenvalues λ_k which decrease at a rate of approximately k^{-x}. The rate of decrease in the eigenvalues is an indication of the amount of randomness the random process contains. Thus, the minimum achievable expected distortion depends crucially on the rate of decrease parameter x. The lower (upper) bound on the eigenvalues in (12) will be used to calculate the lower (upper) bound on the minimum achievable expected distortion. Conditions 2 and 3 are needed because instead of the random process itself that is of interest to the collector node, the collector node, at best, can know only the sampled values of the random process. How well the the entire process can be approximated from its samples is of great importance in obtaining quantitative results. Lipschitz conditions describe the quality of this approximation well. By condition 3, we require the variation in the eigenfunction ϕ_k to be no faster than k^τ. We note that the well-known trigonometric basis satisfies this condition.

We also note that our conditions are quite general. Many random processes satisfy these conditions, including the Gauss-Markov process, Brownian motion process, centered Brownian bridge, etc. For example, a Gauss-Markov process, also known as the Ornstein-Uhlenbeck process [14, 15], is defined as a random process that is stationary, Gaussian, Markovian, and continuous in probability. It is known that the autocorrelation function of this process is [16–18]

$$K(t,s) = \frac{\sigma^2}{2\eta} e^{-\eta|t-s|} \tag{16}$$

The Karhunen-Loeve expansion of the Gauss-Markov process yields the eigenfunctions $\{\phi_k(t)\}_{k=0}^{\infty}$

$$\phi_k(t) = b_k \left(\cos\sqrt{\frac{\sigma^2}{\lambda_k} - \eta^2}\, t + \frac{\eta}{\sqrt{\frac{\sigma^2}{\lambda_k} - \eta^2}} \sin\sqrt{\frac{\sigma^2}{\lambda_k} - \eta^2}\, t \right) \tag{17}$$

where $\{\lambda_k\}_{k=0}^{\infty}$ are the corresponding eigenvalues and b_k are positive constants chosen such that the eigenfunctions $\phi_k(t)$ have unit energy. It can be shown that $\{\lambda_k\}_{k=0}^{\infty}$ may be bounded as

$$\lambda'_k \le \lambda_k \le \lambda''_k \tag{18}$$

where $\{\lambda'_k\}_{k=1}^{\infty}$ is defined as

$$\lambda'_k = \begin{cases} \lambda_k, & k \le K_0 \\ \frac{\sigma^2 T_0^2}{(k+1)^2 \pi^2}, & k > K_0 \end{cases} \tag{19}$$

with $K_0 = \max\left(2, \left\lfloor \frac{\eta^2 T_0^2}{\pi^2} - \frac{3}{4} \right\rfloor\right)$, and $\{\lambda_k''\}_{k=1}^{\infty}$ is defined as

$$\lambda_k'' = \begin{cases} \lambda_k, & k \le K_0 \\ \frac{\sigma^2 T_0^2}{(k-1)^2 \pi^2}, & k > K_0 \end{cases} \tag{20}$$

Thus, we observe that the Gauss-Markov process satisfies the conditions defined in this section with $x = 2$ and $\alpha = \beta = \tau = \gamma = 1$. In fact, in a preliminary conference version of our work [1], we focused specifically on the Gauss-Markov process and presented results similar to those here. We also note, as discussed in the Introduction section, that the channel model in [1] is somewhat different than here, and therefore the order-optimal achievability schemes in [1] and here are different.

The lower and upper bounds on the minimum achievable expected distortion will be calculated using $\{\lambda_k'\}_{k=0}^{\infty}$ and $\{\lambda_k''\}_{k=0}^{\infty}$, respectively. Some properties of $\{\lambda_k'\}_{k=0}^{\infty}$ and $\{\lambda_k''\}_{k=0}^{\infty}$ which will be used in later proofs are stated in Lemmas 5 and 6 and proved in Appendix 9.1.

4 A Lower Bound on the Achievable Distortion

4.1 Arbitrary Gaussian Random Processes

A lower bound is obtained by assuming that all of the sensor nodes know the random process exactly, and, the sensor network forms an N-transmit 1-receive antenna point-to-point system to transmit the random process to the collector node. Let C_u^N be the capacity of this point-to-point system and $D_p(R)$ be the distortion-rate function of the random process $S(t)$ [19]. In this point-to-point system, the separation principle holds, and therefore

$$D^N \ge D_p(C_u^N) \tag{21}$$

To evaluate $D_p(C_u^N)$, we first find the distortion-rate function, $D_p(R)$, of $S(t)$ [19, Section 4.5] as,

$$R(\theta) = \sum_{k=0}^{\infty} \max\left(0, \frac{1}{2}\log\left(\frac{\lambda_k}{\theta}\right)\right) \tag{22}$$

and

$$D(\theta) = T_0^{-1} \sum_{k=0}^{\infty} \min(\theta, \lambda_k) \tag{23}$$

Next, we find C_u^N, the capacity of the N-transmit 1-receive antenna point-to-point system [20] as,

$$C_u^N = \frac{1}{2}\log\left(1 + \sum_{i=1}^{N} h_{i0}^2 P(N)\right) \tag{24}$$

To see how C_u^N changes with N, using (24) and (4), we can lower and upper bound C_u^N as

$$\frac{1}{2}\log\left(1 + \bar{h}_l^2 NP(N)\right) \le C_u^N \le \frac{1}{2}\log\left(1 + \bar{h}_u^2 NP(N)\right) \tag{25}$$

For arbitrary Gaussian random processes, a lower bound on the minimum achievable expected distortion is

$$D_l^N = D_p(C_u^N) \tag{26}$$

4.2 The Class of Gaussian Random Processes in $\mathcal{A}$

Next, we evaluate $D_p(C_u^N)$ for the class of Gaussian random processes in $\mathcal{A}$. Based on the structure of the eigenvalues in (10) and (12), and the properties of $\{\lambda'_k\}_{k=0}^{\infty}$ in Lemma 5 in Appendix 9.1, we have the following lemma.

Lemma 1 *For Gaussian random processes in $\mathcal{A}$, for any constant $0 < \kappa < 1$, we have*

$$R(\theta) \ge \frac{\kappa x d^{\frac{1}{x}}}{2}\theta^{-\frac{1}{x}} \tag{27}$$

$$D(\theta) \ge \kappa\left(1 + \frac{\kappa}{x-1}\right)\frac{d^{\frac{1}{x}}}{T_0}\theta^{1-\frac{1}{x}} \tag{28}$$

when θ is small enough .

A proof of Lemma 1 is provided in Appendix 9.2.

Using Lemma 1, we present in the next theorem a lower bound for the distortion-rate function of the random process.

Theorem 1 *For Gaussian random processes in $\mathcal{A}$, for any constant $0 < \kappa < 1$, we have*

$$D_p(R) \ge \kappa\left(1 + \frac{\kappa}{x-1}\right)\left(\frac{\kappa x}{2}\right)^{x-1}\frac{d}{T_0}R^{1-x} \tag{29}$$

when R is large enough.

A proof of Theorem 1 is provided in Appendix 9.3.

We will divide our discussion into two separate cases based on the total power, $P(N)$. For the first case, $P(N)$ is such that

$$\lim_{N\to\infty} \frac{1}{NP(N)} = 0 \tag{30}$$

The cases $P(N) = NP_{\text{ind}}$ and $P(N) = P_{\text{tot}}$ are included in $P(N)$ satisfying (30).

Theorem 2 *For Gaussian random processes in $\mathcal{A}$, when $P(N)$ is such that (30) is satisfied, for any constant $0 < \kappa < 1$, a lower bound on the minimum achievable expected distortion is*

$$D_l^N = D_p(C_u^N) \geq \kappa^2 \left(1 + \frac{\kappa}{x-1}\right) (\kappa x)^{x-1} \frac{d}{T_0} \left(\frac{1}{\log\left(NP(N)\right)}\right)^{x-1} \tag{31}$$

when N is large enough.

A proof of Theorem 2 is provided in Appendix 9.4.

Hence, when total power $P(N)$ satisfies (30), a lower bound on the achievable distortion is

$$\Theta\left(\left(\frac{1}{\log(NP(N))}\right)^{x-1}\right) \tag{32}$$

For the second case, $P(N)$ is such that (30) is not satisfied. In this case, C_u^N is either a constant independent of N or goes to zero as N goes to infinity. The minimum achievable distortion does not go to zero with increasing N.

Therefore, for all possible total power $P(N)$, a lower bound on the distortion is

$$\Theta\left(\min\left(\left(\frac{1}{\log(NP(N))}\right)^{x-1}, 1\right)\right) \tag{33}$$

When the total power $P(N)$ grows almost exponentially with the number of nodes, the lower bound on the minimum achievable expected distortion in (33) decreases inverse polynomially with N. Even though this provides excellent distortion performance, it is impractical since sensor nodes are low energy devices and it is often difficult, if not impossible, to replenish their batteries. When the total power $P(N)$ is such that (30) is not satisfied, the transmission power is so low that the communication channels between the sensors and the collector node are as if they do not exist. From (33), the lower bound on the estimation error in this case is on the order of 1, which is equivalent to the collector node blindly estimating $S(t) = 0$ for all $t \in [0, T_0]$. Even though the consumed total power $P(N)$ is very low in this case, the performance of the sensor network is unacceptable; even the lower bound on the minimum achievable expected distortion does not decrease to zero with the increasing number of nodes. For practically meaningful total power values, including the cases of $P(N) = NP_{\text{ind}}$ and $P(N) = P_{\text{tot}}$, the lower bound on the minimum achievable expected distortion in (33) decays to zero at the rate of

$$\frac{1}{(\log N)^{x-1}} \tag{34}$$

5 An Upper Bound on the Achievable Distortion

5.1 Arbitrary Gaussian Random Processes

Any distortion found by using any achievability scheme will serve as an upper bound for the minimum achievable expected distortion. We consider the following separation-based achievable scheme. First, we perform multi-terminal rate-distortion coding at all sensor nodes using [11, Theorem 1]. After obtaining the indices of the rate-distortion codes, we transmit the indices as independent messages using the amplify-and-forward method introduced in [12]. The distortion obtained using this scheme will be denoted as D_u^N.

We apply [11, Theorem 1], generalized to N sensor nodes in [21, Theorem 1], to obtain an achievable rate-distortion point.

Theorem 3 *For all Gaussian random processes, if the individual rates are equal, the following sum rate and distortion are achievable,*

$$D_a^N(\theta') = \frac{1}{T_0}\int_0^{T_0} \left(K(t,t) - \frac{T_0}{N-1}\boldsymbol{\rho}_N^T(t)\left(\Sigma_N' + \theta' I\right)^{-1}\boldsymbol{\rho}_N(t)\right) dt \tag{35}$$

$$R_a^N(\theta') = \sum_{k=0}^{N-1} \frac{1}{2}\log\left(1 + \frac{\mu_k^{(N)'}}{\theta'}\right) \tag{36}$$

where

$$\boldsymbol{\rho}_N(t) = \Big[K\left(t,0\right) \quad K\left(t, \tfrac{T_0}{N-1}\right) \quad K\left(t, \tfrac{2T_0}{N-1}\right) \cdots \quad K\left(t, T_0\right)\Big]^T \tag{37}$$

and

$$\begin{aligned}\Sigma_N &= E[\mathbf{S}_N\mathbf{S}_N^T] \\ &= \begin{bmatrix} K(0,0) & K\left(0,\frac{T_0}{N-1}\right) & \cdots & K\left(0,T_0\right) \\ K\left(\frac{T_0}{N-1},0\right) & K\left(\frac{T_0}{N-1},\frac{T_0}{N-1}\right) & \cdots & K\left(\frac{T_0}{N-1},T_0\right) \\ \vdots & \vdots & \vdots & \vdots \\ K(T_0,0) & K\left(T_0,\frac{T_0}{N-1}\right) & \cdots & K(T_0,T_0) \end{bmatrix}\end{aligned} \tag{38}$$

and $\Sigma_N' = \frac{T_0}{N-1}\Sigma_N$ *and* $\mu_0^{(N)'}, \mu_1^{(N)'}, \cdots, \mu_{N-1}^{(N)'}$ *are the eigenvalues of* Σ_N'.

A proof of Theorem 3 is provided in Appendix 9.5.

We further evaluate $D_a^N(\theta')$ in the next lemma.

Lemma 2 *For all Gaussian random processes, we have*

$$D_a^N(\theta') \leq 2A^{(N)} + B^{(N)} + D_b^N(\theta') \tag{39}$$

where $A^{(N)}$, $B^{(N)}$ *and* $D_b^N(\theta')$ *are defined as*

$$\begin{aligned} A^{(N)} =& \frac{1}{T_0} \sum_{i=1}^{N-1} \int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0} \left(K(t,t) - K\left(\frac{i-1}{N-1}T_0, \frac{i-1}{N-1}T_0\right)\right) dt \\ &+ \frac{2}{T_0} \sum_{i=1}^{N-1} \int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0} \left(\boldsymbol{\rho}_N\left(\frac{i-1}{N-1}T_0\right) - \boldsymbol{\rho}_N(t)\right)_i dt \end{aligned} \tag{40}$$

and

$$B^{(N)} = \frac{2}{T_0} \sum_{i=1}^{N-1} \int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0} \left\| \boldsymbol{\rho}_N\left(\frac{i-1}{N-1}T_0\right) - \boldsymbol{\rho}_N(t)\right\| dt \tag{41}$$

and

$$D_b^N(\theta') = \frac{1}{T_0} \sum_{k=0}^{N-1} \left(\frac{1}{\theta'} + \frac{1}{\mu_k^{(N)'}} \right)^{-1} \tag{42}$$

respectively.

A proof of Lemma 2 is provided in Appendix 9.6. Lemma 2 tells us that the expected distortion achieved by using the separation-based scheme is upper bounded by the sum of three types of distortion. The first two types of distortion, $A^{(N)}$ and $B^{(N)}$, have nothing to do with the rate and only depend on how well the samples approximate the entire random process. The third distortion, $D_b^N(\theta')$, depends on the rate through variable θ'.

Now, we determine an achievable rate for the communication channel from the sensor nodes to the collector node. The channel in its nature is a multiple access channel with potential cooperation between the transmitters. The capacity region for this channel is not known. We get an achievable sum rate, with identical individual rates, for this channel by using the idea presented in [12].

Theorem 4 *When the total power* $P(N)$ *is such that there exists an* $\epsilon > 0$ *where*

$$\lim_{N\to\infty} P(N) N^{\frac{1}{2}-\epsilon} > 1 \tag{43}$$

for any constant $0 < \kappa < 1$*, the following sum rate is achievable,*

$$C_a^N = \kappa\nu \log(NP(N)) \tag{44}$$

where ν *is a positive constant independent of* N*,*

$$\nu = \min\left(\frac{\epsilon}{1+2\epsilon}, \frac{1}{4}\right) \tag{45}$$

when N *is large enough. The individual rates of the sensor nodes are the same. Otherwise, the sum rate approaches a positive constant or zero as* $N \to \infty$*.*

A proof of Theorem 4 is provided in Appendix 9.7. Theorem 4 shows that when the total power is such that (43) is satisfied, the achievable rate increases with N. Furthermore, the achievable rate is the same as the upper bound on the achievable sum rate in (25) order-wise. Otherwise, the achievable rate is either a positive constant or decreases to zero, which will result in poor estimation performance at the collector node.

The function $R_a^N(\theta')$ is a strictly decreasing function of θ', thus, the inverse function exists, which we will denote as $\theta_a^N(R)$. Let us define $D_a(R)$ as the composition of the two functions $D_a^N(\theta')$ and $\theta_a^N(R)$, i.e.,

$$D_a(R) = D_a^N(\theta_a^N(R)) \tag{46}$$

An upper bound on the minimum achievable distortion, i.e., the achievable distortion by the separation-based scheme described above, is

$$D_u^N = D_a\left(C_a^N\right) \tag{47}$$

We will perform this calculation when the underlying random process is in $\mathcal{A}$.

5.2 The Class of Gaussian Random Processes in $\mathcal{A}$

We analyze the three types of distortion in (39) for Gaussian random processes in $\mathcal{A}$. We will focus on $A^{(N)}$ and $B^{(N)}$ in Lemma 3, and on $D_b^N(\theta')$ in Lemma 4.

Lemma 3 *For Gaussian random processes in* $\mathcal{A}$*, we have*

$$A^{(N)} = O\left(N^{-\alpha}\right) \tag{48}$$

$$B^{(N)} = O\left(N^{\frac{1}{2}-\alpha}\right) \tag{49}$$

A proof of Lemma 3 is provided in Appendix 9.8. The result depends crucially on condition 2 in the definition of $\mathcal{A}$ in Section 3. Note that since $1/2 < \alpha \le 1$, both $A^{(N)}$ and $B^{(N)}$

decrease to zero inverse polynomially as N goes to infinity.

It remains to calculate the functions $R_a^N(\theta')$ and $D_b^N(\theta')$ for random processes in $\mathcal{A}$. To do so, we need some properties of $\{\mu_k^{(N)'}\}_{k=0}^{N-1}$ which are stated in Lemmas 7 and 8 and proved in Appendix 9.9. Lemma 7 is of great importance, as it serves as a tool to link $\{\mu_k^{(N)'}\}_{k=0}^{N-1}$ to $\{\lambda_k\}_{k=0}^{\infty}$, which is used in the derivation of the lower bound in Section 4, through the lower and upper bounds $\{\lambda'_k\}_{k=0}^{\infty}$ and $\{\lambda''_k\}_{k=0}^{\infty}$. Armed with the properties of $\mu_k^{(N)'}$, λ'_k and λ''_k in Lemmas 5, 6, 7 and 8 in Appendices 9.1 and 9.9, we can show the following lemma. First, we define two sequences ϑ_L^N and ϑ_U^N, which are functions of N, that satisfy

$$\lim_{N\to\infty} \frac{1}{\vartheta_L^N N^{\min\left(\frac{x\gamma}{2\tau}, \frac{\alpha x}{x-1}, \frac{\beta x}{x+\tau+1}\right)}} = 0, \qquad \lim_{N\to\infty} \vartheta_U^N = 0 \tag{50}$$

Lemma 4 *For Gaussian random processes in $\mathcal{A}$, for any constant $0 < \kappa < 1$, lower and upper bounds for the function $R_a^N(\theta')$ are*

$$\frac{\kappa x d^{\frac{1}{x}}}{4}\theta'^{-\frac{1}{x}} \leq R_a^N(\theta') \leq \frac{d^{\frac{1}{x}}\left(x^2-(1-\log 2)x+(1-\log 2)\right)}{2(x-1)\kappa^2}\theta'^{-\frac{1}{x}} \tag{51}$$

and an upper bound for the function $D_b^N(\theta')$ is

$$D_b^N(\theta') \leq \frac{d^{\frac{1}{x}}\left(1+\kappa^2(x-1)\right)}{\kappa^3(x-1)T_0}\theta'^{1-\frac{1}{x}} \tag{52}$$

for $\theta' \in [\vartheta_L^N, \vartheta_U^N]$ and N large enough.

A proof of Lemma 4 is provided in Appendix 9.10. The proof of Lemma 4 uses conditions 1, 2 and 3 in Section 3. Let us define a sequence ϑ_{LL}^N, which is a function of N, that satisfies

$$\lim_{N\to\infty} \frac{1}{\vartheta_{LL}^N N^{\min\left(\frac{x\gamma}{2\tau}, \frac{(\alpha-1/2)x}{x-1}, \frac{\beta x}{x+\tau+1}\right)}} = 0 \tag{53}$$

Combining (39), (48), (49), (51) and (52), we have the following theorem.

Theorem 5 *For Gaussian random processes in $\mathcal{A}$, for any constant $0 < \kappa < 1$, the achievable distortion-rate function, $D_a(R)$, is upper bounded as*

$$D_a(R) \leq \frac{d(1+\kappa^2(x-1))\left(x^2-(1-\log 2)x+(1-\log 2)\right)^{x-1}}{T_0\kappa^{2x+2}2^{x-1}(x-1)^x}R^{1-x} \tag{54}$$

for R in the interval of

$$\left[\frac{d^{\frac{1}{x}}\left(x^2-(1-\log 2)x+(1-\log 2)\right)}{2(x-1)\kappa^2}\left(\vartheta_U^N\right)^{-\frac{1}{x}}, \frac{\kappa x d^{\frac{1}{x}}}{4}\left(\vartheta_{LL}^N\right)^{-\frac{1}{x}}\right] \tag{55}$$

when N is large enough.

A proof of Theorem 5 is provided in Appendix 9.11. This theorem shows that when R is in the interval (55), the achievable distortion-rate function is the same as the lower bound on the distortion-rate function in (29) order-wise.

Theorem 6 *For Gaussian random processes in $\mathcal{A}$, when the sum power constraint satisfies (43) and*

$$\lim_{N\to\infty} \frac{NP(N)}{e^{N^{\min\left(\frac{\gamma}{2\tau}, \frac{2\alpha-1}{2(x-1)}, \frac{\beta}{x+\tau+1}\right)}}} = 0 \tag{56}$$

an upper bound on the minimum achievable expected distortion, or equivalently, the achievable rate in the separation-based scheme, is

$$D_u^N = D_a\left(C_a^N\right) \tag{57}$$

$$\leq \frac{d(1+\kappa^2(x-1))\left(x^2-(1-\log 2)x+(1-\log 2)\right)^{x-1}}{T_0\kappa^{3x+1}2^{x-1}(x-1)^x\nu^{x-1}}\left(\frac{1}{\log(NP(N))}\right)^{x-1} \tag{58}$$

when N is large enough.

A proof of Theorem 6 is provided in Appendix 9.12. Theorem 6 implies that, when the sum power constraint satisfies (43) and (56), an upper bound on the minimum achievable expected distortion is

$$\Theta\left(\left(\frac{1}{\log(NP(N))}\right)^{x-1}\right) \tag{59}$$

For the interesting cases of $P(N) = NP_{\text{ind}}$ and $P(N) = P_{\text{tot}}$, the upper bound on the minimum achievable expected distortion decays to zero at the rate of

$$\frac{1}{(\log N)^{x-1}} \tag{60}$$

When the sum power constraint is such that (43) is not satisfied, an upper bound on the minimum achievable expected distortion is $\Theta(1)$.

6 Comparison of the Lower and Upper Bounds for Gaussian Random Processes in $\mathcal{A}$

6.1 Order-wise Comparison of Lower and Upper Bounds

In this section, we compare the lower bound in (33) and the upper bound in (59). When the total power is large, i.e., $P(N)$ is so large that (56) is not satisfied, our methods in finding the upper bound do not apply. Even though our lower bound in (33) is valid, we have not shown whether the lower and upper bounds meet. However, in this case, $P(N)$ is larger than $\frac{e^{N^{\min\left(\frac{\gamma}{2\tau},\frac{2\alpha-1}{2(x-1)},\frac{\beta}{x+\tau+1}\right)}}}{N}$, and this region of total power is not of practical interest.

When the total power is medium, i.e., $P(N)$ is in the wide range of $N^{-1/2+\epsilon}$ to $\frac{e^{N^{\min\left(\frac{\gamma}{2\tau},\frac{2\alpha-1}{2(x-1)},\frac{\beta}{x+\tau+1}\right)}}}{N}$, our lower and upper bounds do meet and the minimum achievable expected distortion is

$$D^N = \Theta\left(\frac{1}{\left(\log(NP(N))\right)^{x-1}}\right) \tag{61}$$

The order-optimal achievability scheme is a separation-based scheme, which uses distributed rate-distortion coding as described in [11] and optimal single-user channel coding with amplify-and-forward method as described in [12]. In fact, when the total power is medium, as shown in (29) and (54), lower and upper bounds on the distortion-rate function, $D_p(R)$ and $D_a(R)$ coincide order-wise. In addition, as shown in (25) and (44), the lower and upper bounds on the achievable sum rate, C_a^N and C_u^N, coincide order-wise as well. The practically interesting cases of $P(N) = NP_{\text{ind}}$ and $P(N) = P_{\text{tot}}$ fall into this region of medium total power. In both of these cases, the minimum achievable expected distortion decreases to zero at the rate of

$$\frac{1}{\left(\log N\right)^{x-1}} \tag{62}$$

Hence, the total power $P(N) = P_{\text{tot}}$ performs as well as $P(N) = NP_{\text{ind}}$ "order-wise", and therefore, in practice we may prefer to choose $P(N) = P_{\text{tot}}$. In fact, we can decrease the total power to $P(N) = N^{-1/3}$ and the minimum achievable distortion will still decrease to zero at the rate in (62).

When the total power is small, i.e., $P(N)$ ranges from N^{-1} to $N^{-1/2}$, our lower and upper bounds do not meet. Our lower bound in (33) decreases to zero as $\frac{1}{(\log N)^{x-1}}$ but our upper bound is a non-zero constant. The main discrepancy between our lower and upper bounds comes from the gap between the lower and upper bounds on the sum capacities, C_a^N and C_u^N, for a cooperative multiple access channel. In fact, when the total power is small, as shown in (29) and (54), lower and upper bounds on the distortion-rate function, $D_p(R)$ and $D_a(R)$ still coincide order-wise. This total power region should be of practical interest, because in this region, the sum power constraint is quite low, and yet the lower bound on the distortion is of the same order as one would obtain with any $P(N)$ which increases polynomially with N. Hence, from the lower bound, it seems that this region potentially has good performance. However, our separation-based upper bound does not meet the lower bound, and whether the lower bound can be achieved remains an open problem.

When the total power is very small, i.e., $P(N)$ is less than N^{-1}, our lower and upper bounds meet and the minimum achievable expected distortion is a constant that does not decrease to zero with increasing N. This case is not of practical interest because of the unacceptable distortion.

In the case of Gauss-Markov random process, we have $x = 2$ and $\alpha = \beta = \tau = \gamma = 1$. Inserting these values into the above results, we see that in the medium total power region, i.e., $P(N)$ is in the wide range of $N^{-1/2+\epsilon}$ to $\frac{e^{N^{1/4}}}{N}$, the minimum achievable expected distortion is

$$D^N = \Theta\left(\frac{1}{\log(NP(N))}\right) \tag{63}$$

For the Gauss-Markov random process, in the cases of $P(N) = NP_{\text{ind}}$ and $P(N) = P_{\text{tot}}$, the minimum achievable expected distortion decreases to zero at the rate of

$$\frac{1}{\log N} \tag{64}$$

The conclusions in (63) and (64) were derived in [1] under a different channel assumption. For the channel assumption in [1], the order-optimal achievability scheme was determined to be a decode-and-forward based scheme. The range of medium power constraints was shown to be slightly larger in [1], i.e., $P(N)$ in the range of $N^{-1/2+\epsilon}$ to $\frac{e^{N^{1/3}}}{N}$, and this is because it was specifically derived for the Gauss-Markov process, instead of general Gaussian random processes as in this work.

6.2 Comparison of the Constants in the Lower and Upper Bounds

Though the lower and upper bounds meet order-wise in a wide range of total power constraints, the constants in front of them are different and we aim to compare these constants for various total power constraints in this section.

Combining (31) and (58), when $P(N)$ satisfies (43) and (56), the minimum distortion D^N satisfies

$$\kappa^2 \left(1 + \frac{\kappa}{x-1}\right) (\kappa x)^{x-1} \frac{d}{T_0} \left(\frac{1}{\log\left(NP(N)\right)}\right)^{x-1} \leq D^N$$

$$\leq \frac{d(1+\kappa^2(x-1))\left(x^2-(1-\log 2)x+(1-\log 2)\right)^{x-1}}{T_0 \kappa^{3x+1} 2^{x-1}(x-1)^x \nu^{x-1}} \left(\frac{1}{\log(NP(N))}\right)^{x-1} \tag{65}$$

Note that κ can be made as close to 1 as possible for large enough N. Let $\pi(x, \nu)$ be the ratio of the constant in the lower bound and the constant in the upper bound when N is large enough. Then,

$$\pi(x, \nu) = (2\nu)^{x-1} \left(\frac{x^2 - x}{x^2 - (1-\log 2)x + (1-\log 2)}\right)^{x-1} \tag{66}$$

Here, x is a parameter of the underlying Gaussian random process and ν depends on the total power constraint of the sensor nodes, $P(N)$. It is straightforward to see that since from (45), $\nu \leq 1/4$, $\pi(x, \nu)$ is a monotonically decreasing function of x for a fixed ν. Hence, we conclude that the constants in front of the lower and upper bounds differ more as x gets large. Since x is an indication of how much randomness the random process contains, this means that the more random the random process, the more the constants in the lower and upper bounds meet. For a fixed underlying random process, i.e., for a fixed x, $\pi(x, \nu)$ is a decreasing function of ν. This means that the less the total power we have, the more different the constants will be.

In the Gauss-Markov random process, $x = 2$. When $P(N) = NP_{\text{ind}}$ and $P(N) = P_{\text{tot}}$, the ratio of the two constants is

$$\pi(2, 1/4) = \frac{1}{3 + \log 2} \simeq 0.2708 \tag{67}$$

When $P(N) = N^{-\omega}$, $0 < \omega < \frac{1}{2}$, the ratio of the two constants is

$$\pi\left(2, \frac{1}{2} - \frac{1}{4}\frac{1}{1-\omega}\right) = \left(\frac{1}{2} - \frac{1}{4}\frac{1}{1-\omega}\right) \frac{4}{3+\log 2} \tag{68}$$

For example, when $P(N) = N^{-1/3}$, the ratio of the constants is

$$\pi\left(2, 1/8\right) = \frac{1}{2}\pi(2, 1/4) \simeq 0.1354 \tag{69}$$

7 Further Remarks

We have shown that the minimum achievable expected distortion behaves order-wise as

$$\Theta\left(\left(\frac{1}{\log(NP(N))}\right)^{x-1}\right) \tag{70}$$

Due to the order-optimality of separation, this result can be generalized straightforwardly to several other scenarios.

The result in (70) still holds when we allow the collector node to use its transmit antenna with an arbitrary power constraint. The collector node, using its transmit antenna, can send some form of feedback to the sensor nodes. However, the lower bound on the minimum distortion remains unchanged in this case, because in deriving our lower bound, we assumed that all sensor nodes know the entire random process, thus, forming a point-to-point system. In a point-to-point system, feedback, perfect or not, does not change the capacity. Meanwhile, our upper bound is still valid, as in this achievable scheme, we choose not to utilize the feedback link. Hence, our result in (70) remains valid. For similar reasons, our result in (70) remains valid, when we consider a sum power constraint $P(N)$, instead of individual identical power constraints of $P(N)/N$ for all sensors.

The result in (70) still holds when we allow K channel uses per realization of the random process, where K is a constant independent of N. This is because both lower and upper bounds are derived using separation-based schemes. The minimum achievable distortion still behaves as (70), and the number K will only effect the constant in front. Due to the same reasoning, the minimum achievable distortion behaves as (70) when we allow multiple transmit and receive antennas at each node, as long as the number of antennas on each node is a constant, independent of N.

8 Conclusions

In this paper, we investigated the performance of dense sensor networks by studying the joint source-channel coding problem. We provided lower and upper bounds for the minimum achievable expected distortion when the underlying random process is Gaussian. When the random process satisfies some general conditions, we evaluated the lower and upper bounds explicitly, and showed that they are both of order $\frac{1}{(\log(NP(N)))^{x-1}}$ for a wide range of total power ranging from $N^{-\frac{1}{2}+\epsilon}$ to $\frac{e^{N^{\min\left(\frac{\gamma}{2\tau},\frac{2\alpha-1}{2(x-1)},\frac{\beta}{x+\tau+1}\right)}}}{N}$. In the most interesting cases when the total power is a constant or grows linearly with N, the minimum achievable expected distortion decreases to zero at the rate of $\frac{1}{(\log N)^{x-1}}$. For random processes that satisfy these general conditions, under these power constraints, we have found that an order-optimal scheme is a separation-based scheme, that is composed of distributed rate-distortion coding [11] and amplify-and-forward channel coding [12].

9 Appendix

9.1 Some properties of λ'_k and λ''_k

In this subsection, we provide two lemmas which characterize some properties of $\{\lambda'_k\}_{k=0}^{\infty}$ and $\{\lambda''_k\}_{k=0}^{\infty}$, defined in (10) and (11), which will be useful in deriving our main results.

Lemma 5 *For any constant* $0 < \kappa < 1$*, we have*

$$\sum_{k=\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} - c_l + 1 \right\rfloor}^{\infty} \lambda'_k \geq \frac{\kappa d^{\frac{1}{x}}}{(x-1)} \theta^{1-\frac{1}{x}} \tag{71}$$

and

$$\sum_{k=0}^{\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} - c_l \right\rfloor} \frac{1}{2} \log\left(\frac{\lambda'_k}{\theta}\right) \geq \frac{\kappa x d^{\frac{1}{x}}}{2} \theta^{-\frac{1}{x}} \tag{72}$$

when θ is small enough.

Lemma 6 *For any constant* $0 < \kappa < 1$*, we have*

$$\sum_{k=\left\lfloor \left(\frac{d}{\theta}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{\infty} \lambda''_k \leq \frac{d^{\frac{1}{x}}}{(x-1)\kappa} \theta^{1-\frac{1}{x}} \tag{73}$$

and

$$\sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta}\right)^{\frac{1}{x}} + c_u \right\rfloor} \frac{1}{2} \log\left(1 + \frac{\lambda''_k}{\theta}\right) \leq \left(\frac{\log 2 + x}{2\kappa}\right) d^{\frac{1}{x}} \theta^{-\frac{1}{x}} \tag{74}$$

when θ is small enough.

9.1.1 Proof of Lemma 5

We will first prove (71).

$$\sum_{k=\left\lfloor\frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}}-c_l+1\right\rfloor}^{\infty}\lambda'_k = \sum_{k=\left\lfloor\frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}}-c_l+1\right\rfloor}^{\infty}\frac{d}{(k+c_l)^x} \tag{75}$$

$$= d\sum_{k=\left\lfloor\frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}}+1\right\rfloor}^{\infty}\frac{1}{k^x} \tag{76}$$

$$\geq \frac{d}{x-1}\frac{1}{\left\lfloor\frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}}+1\right\rfloor^{x-1}} \tag{77}$$

$$\geq \frac{\kappa d^{\frac{1}{x}}}{(x-1)}\theta^{1-\frac{1}{x}} \tag{78}$$

where (75) is true when θ is small enough, more specifically, when $\left\lfloor\frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}}-c_l+1\right\rfloor > K_0$. We have (77) because of the inequality

$$\sum_{k=n}^{\infty}\frac{1}{k^x} \geq \int_n^{\infty}\frac{1}{y^x}dy = \frac{1}{(x-1)n^{x-1}} \tag{79}$$

and (78) is true when θ is small enough, i.e., for any $0 < \kappa < 1$, there exists a $\theta_0(\kappa) > 0$ such that when $0 < \theta \leq \theta_0(\kappa)$, (78) is true.

Next, we will prove (72).

$$\sum_{k=0}^{\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} - c_l \right\rfloor} \frac{1}{2} \log\left(\frac{\lambda'_k}{\theta}\right)$$

$$=\sum_{k=0}^{K_0} \frac{1}{2}\log\left(\frac{\lambda_k}{\theta}\right) + \sum_{k=K_0+1}^{\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor - c_l} \frac{1}{2}\log\left(\frac{d}{\left(k+c_l\right)^x \theta}\right) \tag{80}$$

$$=\sum_{k=0}^{K_0} \frac{1}{2}\log\left(\frac{\lambda_k}{\theta}\right) + \sum_{k=K_0+c_l+1}^{\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor} \frac{1}{2}\log\left(\frac{d}{k^x \theta}\right) \tag{81}$$

$$=\sum_{k=0}^{K_0} \frac{1}{2}\log\left(\frac{\lambda_k}{d}\right) + \sum_{k=0}^{K_0} \frac{1}{2}\log\left(\frac{d}{\theta}\right) + \frac{1}{2}\left(\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor - c_l - K_0\right)\log\left(\frac{d}{\theta}\right) - \frac{x}{2}\log \prod_{k=K_0+c_l+1}^{\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor} k \tag{82}$$

$$=\sum_{k=0}^{K_0} \frac{1}{2}\log\left(\frac{\lambda_k}{d}\right) + \frac{1}{2}\left(\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor - c_l + 1\right)\log\left(\frac{d}{\theta}\right) - \frac{x}{2}\log\left(\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor !\right) + \frac{x}{2}\log\left(\left(K_0+c_l\right)!\right) \tag{83}$$

$$\begin{aligned} \geq & \frac{1}{2}\left(\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor - c_l + 1\right)\log\left(\frac{d}{\theta}\right) - \frac{x}{2}\left(\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor + \frac{1}{2}\right)\log\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor + \frac{x}{2}\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor - \frac{x}{24\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor} \\ & + \sum_{k=0}^{K_0} \frac{1}{2}\log\left(\frac{\lambda_k}{d}\right) + \frac{x}{2}\log\left(\left(K_0+c_l\right)!\right) - \frac{x}{4}\log(2\pi) \end{aligned} \tag{84}$$

$$\geq \frac{x}{2}\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor + \frac{x}{2}\left(-c_l + \frac{1}{2}\right)\log\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor - \frac{x}{24\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor} + c_3 \tag{85}$$

$$\geq \frac{\kappa x d^{\frac{1}{x}}}{2}\theta^{-\frac{1}{x}} \tag{86}$$

where (80) is true when θ is small enough, more specifically, when $\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} - c_l \right\rfloor > K_0$. (84) follows by using Stirling's approximation,

$$n! < \sqrt{2\pi} n^{n+\frac{1}{2}} e^{-n+\frac{1}{12n}} \tag{87}$$

(85) follows because c_3 is a constant, independent of θ, defined as

$$c_3 \triangleq \sum_{k=0}^{K_0} \frac{1}{2}\log\left(\frac{\lambda_k}{d}\right) + \frac{x}{2}\log\left((K_0+c_l)!\right) - \frac{x}{4}\log(2\pi) \tag{88}$$

and (86) is true when θ is small enough, i.e., for any $0<\kappa<1$, there exists a $\theta_1(\kappa)>0$ such that when $0<\theta\leq\theta_1(\kappa)$, (86) is true.

Therefore, for any $0<\kappa<1$, (71) and (72) hold when θ is small enough.

9.1.2 Proof of Lemma 6

We will first prove (73).

$$\begin{aligned}
\sum_{k=\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}+c_u\right\rfloor+1}^{\infty} \lambda_k'' &= \sum_{k=\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}+c_u\right\rfloor+1}^{\infty} \frac{d}{(k-c_u)^x} &(89)\\
&= \sum_{k=\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor+1}^{\infty} \frac{d}{k^x} &(90)\\
&= \frac{d}{(x-1)\left(\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\right)^{x-1}} &(91)\\
&\leq \frac{d^{\frac{1}{x}}}{(x-1)\kappa}\theta^{1-\frac{1}{x}} &(92)
\end{aligned}$$

where (89) follows when θ is small enough, more specifically, when $\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}+c_u\right\rfloor+1>K_0$. In obtaining (91) we used

$$\sum_{k=n}^{\infty}\frac{1}{k^x} \leq \int_{n-1}^{\infty}\frac{1}{y^x}dy = \frac{1}{(x-1)(n-1)^{x-1}} \tag{93}$$

and (92) follows when θ is small enough, i.e., for any $0<\kappa<1$, there exists a $\theta_2(\kappa)>0$ such that when $0<\theta\leq\theta_2(\kappa)$, (92) is true.

Next, we will prove (74).

$$
\begin{aligned}
&\sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta}\right)^{\frac{1}{x}}+c_u \right\rfloor} \frac{1}{2}\log\left(1+\frac{\lambda''_k}{\theta}\right)\\
&\quad=\sum_{k=0}^{K_0}\frac{1}{2}\log\left(1+\frac{\lambda_k}{\theta}\right)+\sum_{k=K_0+1}^{\left\lfloor \left(\frac{d}{\theta}\right)^{\frac{1}{x}}+c_u \right\rfloor}\frac{1}{2}\log\left(1+\frac{d}{(k-c_u)^x\theta}\right) && (94)\\
&\quad\leq\sum_{k=0}^{K_0}\frac{1}{2}\log\left(\frac{2\lambda_k}{\theta}\right)+\sum_{k=K_0+1}^{\left\lfloor \left(\frac{d}{\theta}\right)^{\frac{1}{x}}+c_u \right\rfloor}\frac{1}{2}\log\left(\frac{2d}{(k-c_u)^x\theta}\right) && (95)\\
&\quad=\sum_{k=0}^{K_0}\frac{1}{2}\log\left(\frac{2\lambda_k}{\theta}\right)+\sum_{k=c_u+1}^{\left\lfloor \left(\frac{d}{\theta}\right)^{\frac{1}{x}}+c_u \right\rfloor}\frac{1}{2}\log\left(\frac{2d}{(k-c_u)^x\theta}\right)-\sum_{k=c_u+1}^{K_0}\frac{1}{2}\log\left(\frac{2d}{(k-c_u)^x\theta}\right)\\
& && (96)\\
&\quad=\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\frac{1}{2}\log 2-\frac{x}{2}\log\left(\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor!\right)+\frac{1}{2}\left(\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\right)\log\frac{d}{\theta}\\
&\qquad+\frac{c_u+1}{2}\log\frac{d}{\theta}+c_1 && (97)\\
&\quad\leq\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\frac{1}{2}\log 2-\frac{x}{4}\log(2\pi)-\frac{x}{2}\left(\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor+\frac{1}{2}\right)\log\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor+\frac{x}{2}\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\\
&\qquad-\frac{x}{24\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor+2}+\frac{1}{2}\left(\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\right)\log\frac{d}{\theta}+\frac{c_u+1}{2}\log\frac{d}{\theta}+c_1 && (98)\\
&\quad=\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\left(\frac{\log 2+x}{2}\right)+\frac{x}{2}\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\log\frac{\left(\frac{d}{\theta}\right)^{\frac{1}{x}}}{\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor}-\frac{x}{4}\log\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\\
&\qquad+\frac{c_u+1}{2}\log\frac{d}{\theta}-\frac{x}{24\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor+2}-\frac{x}{4}\log(2\pi)+c_1 && (99)\\
&\quad\leq\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\left(\frac{\log 2+x}{2}\right)+\frac{x}{2}\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\log\left(1+\frac{1}{\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor}\right)-\frac{x}{4}\log\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\\
&\qquad+\frac{c_u+1}{2}\log\frac{d}{\theta}-\frac{x}{24\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor+2}-\frac{x}{4}\log(2\pi)+c_1 && (100)\\
&\quad\leq\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor\left(\frac{\log 2+x}{2}\right)-\frac{x}{4}\log\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor+\frac{c_u+1}{2}\log\frac{d}{\theta}-\frac{x}{24\left\lfloor\left(\frac{d}{\theta}\right)^{\frac{1}{x}}\right\rfloor+2}\\
&\qquad-\frac{x}{4}\log(2\pi)+\frac{x}{2}+c_1 && (101)\\
&\quad\leq\left(\frac{\log 2+x}{2\kappa}\right)d^{\frac{1}{x}}\theta^{-\frac{1}{x}} && (102)
\end{aligned}
$$

where (94) is true when θ is small enough, more specifically, when $\left\lfloor \left(\frac{d}{\theta}\right)^{\frac{1}{x}} + c_u \right\rfloor > K_0$. We have (95) because

$$\frac{d}{(k-c_u)^x \theta} > 1 \tag{103}$$

for all k between K_0+1 and $\left\lfloor \left(\frac{d}{\theta}\right)^{\frac{1}{x}} + c_u \right\rfloor$, and when θ is small enough such that

$$\theta \leq \lambda_k, \quad k = 1, 2, \cdots, K_0 \tag{104}$$

We have (97) because we defined

$$c_1 \triangleq \sum_{k=1}^{K_0} \frac{1}{2} \log \frac{2\lambda_k}{d} - \sum_{k=c_u+1}^{K_0} \frac{1}{2} \log \frac{2}{(k-c_u)^x} \tag{105}$$

We used Stirling's approximation,

$$n! > \sqrt{2\pi} n^{n+\frac{1}{2}} e^{-n+\frac{1}{12n+1}} \tag{106}$$

to obtain (98), and (101) follows by using

$$\log(1+x) \leq x, \qquad x \geq 0 \tag{107}$$

(102) follows when θ is small enough, i.e., for any $0 < \kappa < 1$, there exists a $\theta_3(\kappa) > 0$ such that when $0 < \theta \leq \theta_3(\kappa)$, (102) is true.

Therefore, for any $0 < \kappa < 1$, (73) and (74) hold when θ is small enough.

9.2 Proof of Lemma 1

For any $0 < \kappa < 1$, when θ is small enough, the results of Lemma 5 hold.

From (22), we have

$$R(\theta) = \sum_{k=0}^{\infty} \max\left(0, \frac{1}{2}\log\left(\frac{\lambda_k}{\theta}\right)\right) \tag{108}$$

$$\geq \sum_{k=0}^{\infty} \max\left(0, \frac{1}{2}\log\left(\frac{\lambda'_k}{\theta}\right)\right) \tag{109}$$

$$= \sum_{k=0}^{\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} - c_l \right\rfloor} \frac{1}{2}\log\left(\frac{\lambda'_k}{\theta}\right) \tag{110}$$

$$\geq \frac{\kappa x d^{\frac{1}{x}}}{2}\theta^{-\frac{1}{x}} \tag{111}$$

where in (109) we have used the definition of sequence λ'_k in (10) and the observation in (12). (110) follows when θ is small enough, more specifically, when $\theta < \lambda_{K_0}$ and $\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} - c_l \right\rfloor > K_0$. (111) follows from (72) in Lemma 5.

From (23), we have

$$D(\theta) = T_0^{-1} \sum_{k=0}^{\infty} \min(\theta, \lambda_k) \tag{112}$$

$$\geq T_0^{-1} \sum_{k=0}^{\infty} \min(\theta, \lambda'_k) \tag{113}$$

$$= T_0^{-1} \sum_{k=0}^{\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} - c_l \right\rfloor} \theta + T_0^{-1} \sum_{\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} - c_l + 1 \right\rfloor}^{\infty} \lambda'_k \tag{114}$$

$$\geq T_0^{-1}\left(\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} \right\rfloor - c_l + 1\right)\theta + T_0^{-1}\frac{\kappa d^{\frac{1}{x}}}{(x-1)}\theta^{1-\frac{1}{x}} \tag{115}$$

$$\geq \kappa\left(1 + \frac{\kappa}{x-1}\right)\frac{d^{\frac{1}{x}}}{T_0}\theta^{1-\frac{1}{x}} \tag{116}$$

where in (113) we have used the definition of sequence λ'_k in (10) and the observation in (12). (114) follows when θ is small enough, more specifically, when $\theta < \lambda_{K_0}$ and $\left\lfloor \frac{d^{\frac{1}{x}}}{\theta^{\frac{1}{x}}} - c_l + 1 \right\rfloor > K_0$. (115) follows from (71) in Lemma 5. (116) is true for small enough θ, i.e., for any $0 < \kappa < 1$, there exists a $\theta_4(\kappa) > 0$ such that when $0 < \theta \leq \theta_4(\kappa)$, (116) is true.

Therefore, for any $0 < \kappa < 1$, (27) and (28) hold when θ is small enough.

9.3 Proof of Theorem 1

$R(\theta)$ is a strictly decreasing function when $\theta < \lambda_1$. Hence, when $\theta < \lambda_1$, the inverse function $\theta(R)$ exists. For any $0 < \kappa < 1$, when θ is small enough, or equivalently, when R is large enough, from (27) in Lemma 1, we have

$$\theta(R) \geq d \left(\frac{\kappa x}{2}\right)^{x} R^{-x} \tag{117}$$

Using (117) and (28), for any $0 < \kappa < 1$, (29) holds when R is large enough, since $D(\theta)$ is a nondecreasing function of θ.

9.4 Proof of Theorem 2

When $P(N)$ is such that (30) is satisfied, from (25), we see that in this case C_u^N increases monotonically in N. Hence, when N is large enough, C_u^N will be large enough such that Theorem 1 holds. Hence, for any constant $0 < \kappa < 1$, a lower bound on the minimum achievable expected distortion is

$$\begin{aligned} D_l^N &= D_p(C_u^N) &(118)\\ &\geq \kappa \left(1 + \frac{\kappa}{x-1}\right) \left(\frac{\kappa x}{2}\right)^{x-1} \frac{d}{T_0} (C_u^N)^{1-x} &(119)\\ &\geq \kappa \left(1 + \frac{\kappa}{x-1}\right) (\kappa x)^{x-1} \frac{d}{T_0} \left(\frac{1}{\log\left(1 + \bar{h}_u^2 N P(N)\right)}\right)^{x-1} &(120)\\ &\geq \kappa^2 \left(1 + \frac{\kappa}{x-1}\right) (\kappa x)^{x-1} \frac{d}{T_0} \left(\frac{1}{\log\left(N P(N)\right)}\right)^{x-1} &(121) \end{aligned}$$

where (120) follows from (25), and the last step follows when N is large enough, i.e., there exists an $N_0(\kappa) > 0$, such that when $N > N_0(\kappa)$, (121) is true.

Therefore, when $P(N)$ is such that (30) is satisfied, for any $0 < \kappa < 1$, (31) is true when N is large enough.

9.5 Proof of Theorem 3

We restate the generalization of [11, Theorem 1], which appeared in [21, Theorem 1] for N sensor nodes below. This provides us with an achievable rate-distortion point.

Theorem 7 *[11, 21] If the individual rates are equal, a rate-distortion sum rate R_c and distortion D_c are achievable if there exist random variables $T_1, T_2, \cdots, T_N$ with*

$$(S(t), S_{\{i\}^c}, T_{\{i\}^c}) \rightarrow S_i \rightarrow T_i, \qquad i = 1, 2, \cdots, N \tag{122}$$

and an estimator function

$$\hat{S}(t) = g(T_1, T_2, \cdots, T_N) \tag{123}$$

such that

$$R_c \geq I(S_1, S_2, \cdots, S_N; T_1, T_2, \cdots, T_N) \tag{124}$$

$$D_c \geq E[d(S(t), g(T_1, T_2, \cdots, T_N))] \tag{125}$$

We obtain an achievable rate-distortion point when we specify the relationship between $(S(t), \{S_i\}_{i=1}^{\infty}, \{T_i\}_{i=1}^{\infty})$ as

$$T_i = S_i + W_i, \qquad i = 1, 2, \cdots, N \tag{126}$$

where $W_i, i = 1, 2, \cdots, N$, are i.i.d. Gaussian random variables with zero-mean and variance σ_D^2 and independent of everything else. Here, we can adjust σ_D^2 to achieve various feasible rate-distortion points [11].

We choose the MMSE estimator to estimate $S(t)$ from observations $\{T_k\}_{k=1}^{N}$. Hence, the achieved distortion is

$$D_c^N(\sigma_D^2) = \frac{1}{T_0} \int_0^{T_0} \left(K(t,t) - \boldsymbol{\rho}_N^T(t) \left(\Sigma_N + \sigma_D^2 I \right)^{-1} \boldsymbol{\rho}_N(t) \right) dt \tag{127}$$

The sum rate required to achieve this distortion is

$$\begin{aligned} R_c^N(\sigma_D^2) &= I(S_1, S_2, \cdots, S_N; T_1, T_2, \cdots, T_N) \\ &= \frac{1}{2} \log \det \left(I + \frac{1}{\sigma_D^2} \Sigma_N \right) && (128) \\ &= \sum_{k=0}^{N-1} \frac{1}{2} \log \left(1 + \frac{\mu_k^{(N)}}{\sigma_D^2} \right) && (129) \end{aligned}$$

where $\mu_0^{(N)}, \mu_1^{(N)}, \cdots, \mu_{N-1}^{(N)}$ are the eigenvalues of Σ_N.

Next, let $\theta' = \frac{T_0}{N-1}\sigma_D^2$, $\Sigma_N' = \frac{T_0}{N-1}\Sigma_N$ and $\mu_k^{(N)'} = \frac{T_0}{N-1}\mu_k^{(N)}$. We define two functions of θ' as

$$R_a^N(\theta') \triangleq R_c(\sigma_D^2) = \sum_{k=0}^{N-1} \frac{1}{2} \log \left(1 + \frac{\mu_k^{(N)'}}{\theta'} \right) \tag{130}$$

and

$$D_a^N(\theta') \triangleq D_c^N(\sigma_D^2) = \frac{1}{T_0}\int_0^{T_0}\left(K(t,t) - \frac{T_0}{N-1}\boldsymbol{\rho}_N^T(t)\left(\Sigma_N' + \theta' I\right)^{-1}\boldsymbol{\rho}_N(t)\right)dt \qquad (131)$$

and by definition, sum rate $R_a^N(\theta')$ and distortion $D_a^N(\theta')$ are achievable for an arbitrary Gaussian random processes.

9.6 Proof of Lemma 2

Using the matrix inversion lemma [22],

$$\left(\Sigma_N' + \theta' I\right)^{-1} = \Sigma_N'^{-1} - \Sigma_N'^{-1}\left(\frac{1}{\theta'}I + \Sigma_N'^{-1}\right)^{-1}\Sigma_N'^{-1} \qquad (132)$$

we have

$$\begin{aligned} D_a^N(\theta') =& \frac{1}{T_0}\int_0^{T_0}\left(K(t,t) - \frac{T_0}{N-1}\boldsymbol{\rho}_N^T(t)\Sigma_N'^{-1}\boldsymbol{\rho}_N(t)\right)dt \\ &+ \frac{1}{N-1}\int_0^{T_0}\boldsymbol{\rho}_N^T(t)\Sigma_N'^{-1}\left(\frac{1}{\theta'}I + \Sigma_N'^{-1}\right)^{-1}\Sigma_N'^{-1}\boldsymbol{\rho}_N(t)dt \qquad (133) \\ =& D_s^{(N)} + D^{(N)}(\theta') \qquad (134) \end{aligned}$$

where we have defined

$$\begin{aligned} D_s^{(N)} \triangleq& \frac{1}{T_0}\int_0^{T_0}\left(K(t,t) - \frac{T_0}{N-1}\boldsymbol{\rho}_N^T(t)\Sigma_N'^{-1}\boldsymbol{\rho}_N(t)\right)dt \qquad (135) \\ D^{(N)}(\theta') \triangleq& \frac{1}{N-1}\int_0^{T_0}\boldsymbol{\rho}_N^T(t)\Sigma_N'^{-1}\left(\frac{1}{\theta'}I + \Sigma_N'^{-1}\right)^{-1}\Sigma_N'^{-1}\boldsymbol{\rho}_N(t)dt \qquad (136) \end{aligned}$$

We continue evaluating $D^{(N)}(\theta')$,

$$\begin{aligned} &D^{(N)}(\theta') \\ &= \frac{1}{N-1}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(\boldsymbol{\rho}_N^T\left(\frac{i-1}{N-1}T_0\right) - \boldsymbol{\Delta}_i^T(t)\right)\Sigma_N'^{-1}\left(\frac{1}{\theta'}I + \Sigma_N'^{-1}\right)^{-1} \\ &\qquad \Sigma_N'^{-1}\left(\boldsymbol{\rho}_N\left(\frac{i-1}{N-1}T_0\right) - \boldsymbol{\Delta}_i(t)\right)dt \qquad (137) \\ &= \frac{1}{T_0}\sum_{i=1}^{N-1}\left(\left(\frac{1}{\theta'}I + \Sigma_N'^{-1}\right)^{-1}\right)_{(i,i)} - 2\frac{1}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(\left(\frac{1}{\theta'}I + \Sigma_N'^{-1}\right)^{-1}\Sigma_N'^{-1}\boldsymbol{\Delta}_i(t)\right)_i dt \\ &\quad + \frac{1}{N-1}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\boldsymbol{\Delta}_i^T(t)\Sigma_N'^{-1}\left(\frac{1}{\theta'}I + \Sigma_N'^{-1}\right)^{-1}\Sigma_N'^{-1}\boldsymbol{\Delta}_i(t)dt \qquad (138) \end{aligned}$$

where $\mathbf{\Delta}_i(t)$ is defined as

$$\mathbf{\Delta}_i(t) = \boldsymbol{\rho}_N\left(\frac{i-1}{N-1}T_0\right) - \boldsymbol{\rho}_N(t) \tag{139}$$

for $\frac{i-1}{N-1}T_0 \le t \le \frac{i}{N-1}T_0$, and (138) follows based on the fact that

$$\boldsymbol{\rho}_N^T\left(\frac{i-1}{N-1}T_0\right)\Sigma_N^{'-1} = \frac{N-1}{T_0}\mathbf{e}_i \tag{140}$$

where $\mathbf{e}_i$ is the row vector whose i-th entry is 1 and all other entries are 0.

The eigenvalues of $\Sigma_N^{'-1}\left(\frac{1}{\theta'}I + \Sigma_N^{'-1}\right)^{-1}\Sigma_N^{'-1}$ are

$$\frac{\theta'}{\mu_k^{(N)'} + \theta'}\frac{1}{\mu_k^{(N)'}}, \qquad k = 0, 1, \cdots, N-1 \tag{141}$$

which are smaller than the corresponding eigenvalues of $\Sigma_N^{'-1}$, i.e., $\frac{1}{\mu_k^{(N)'}}$. Thus, the third term in (138) is bounded by

$$\begin{aligned}\frac{1}{N-1}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\mathbf{\Delta}_i^T(t)\Sigma_N^{'-1}\left(\frac{1}{\theta'}I + \Sigma_N^{'-1}\right)^{-1}\Sigma_N^{'-1}\mathbf{\Delta}_i(t)dt \\ \le \frac{1}{N-1}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\mathbf{\Delta}_i^T(t)\Sigma_N^{'-1}\mathbf{\Delta}_i(t)dt\end{aligned} \tag{142}$$

To further upper bound the third term in (138), we write

$$D_s^{(N)} = \frac{1}{T_0}\int_0^{T_0}\left(K(t,t) - \frac{T_0}{N-1}\boldsymbol{\rho}_N^T(t)\Sigma_N^{'-1}\boldsymbol{\rho}_N(t)\right)dt \tag{143}$$

$$\begin{aligned}= \frac{1}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\Bigg(K(t,t) - \frac{T_0}{N-1}\left(\boldsymbol{\rho}_N^T\left(\frac{i-1}{N-1}T_0\right) - \mathbf{\Delta}_i(t)^T\right) \\ \Sigma_N^{'-1}\left(\boldsymbol{\rho}_N\left(\frac{i-1}{N-1}T_0\right) - \mathbf{\Delta}_i(t)\right)\Bigg)dt\end{aligned} \tag{144}$$

$$\begin{aligned}= \frac{1}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(K(t,t) - K\left(\frac{i-1}{N-1}T_0, \frac{i-1}{N-1}T_0\right)\right)dt \\ + \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}(\mathbf{\Delta}_i(t))_i\,dt - \frac{1}{N-1}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\mathbf{\Delta}_i(t)^T\Sigma_N^{'-1}\mathbf{\Delta}_i(t)dt\end{aligned} \tag{145}$$

$$= A^{(N)} - \frac{1}{N-1}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\mathbf{\Delta}_i(t)^T\Sigma_N^{'-1}\mathbf{\Delta}_i(t)dt \tag{146}$$

where we have defined

$$A^{(N)} = \frac{1}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(K(t,t)-K\left(\frac{i-1}{N-1}T_0,\frac{i-1}{N-1}T_0\right)\right)dt + \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(\boldsymbol{\Delta}_i(t)\right)_i dt \tag{147}$$

$$\begin{aligned} = & \frac{1}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(K(t,t)-K\left(\frac{i-1}{N-1}T_0,\frac{i-1}{N-1}T_0\right)\right)dt \\ & + \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(\boldsymbol{\rho}_N\left(\frac{i-1}{N-1}T_0\right)-\boldsymbol{\rho}_N(t)\right)_i dt \end{aligned} \tag{148}$$

Then, we have the third term in (138) upper bounded by $A^{(N)}$ because of (142), (146) and the fact that $D_s^{(N)}$ is non-negative, i.e.,

$$\frac{1}{N-1}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\boldsymbol{\Delta}_i^T(t)\Sigma_N^{'-1}\left(\frac{1}{\theta'}I+\Sigma_N^{'-1}\right)^{-1}\Sigma_N^{'-1}\boldsymbol{\Delta}_i(t)dt \leq A^{(N)} \tag{149}$$

Furthermore, we can see from (146) that

$$D_s^{(N)} \leq A^{(N)} \tag{150}$$

Now, we evaluate the second term in (138). Since,

$$\begin{aligned} \left|\left(\left(\frac{1}{\theta'}I+\Sigma_N^{'-1}\right)^{-1}\Sigma_N^{'-1}\boldsymbol{\Delta}_i(t)\right)_i\right| & \leq \left|\left|\left(\frac{1}{\theta'}I+\Sigma_N^{'-1}\right)^{-1}\Sigma_N^{'-1}\boldsymbol{\Delta}_i(t)\right|\right| & (151) \\ & \leq \left|\left|\left(\frac{1}{\theta'}I+\Sigma_N^{'-1}\right)^{-1}\Sigma_N^{'-1}\right|\right|_2 \cdot ||\boldsymbol{\Delta}_i(t)|| & (152) \\ & = \max_{0\leq k\leq N-1}\left(\mu_k^{(N)'}\right)^{-1}\left(\frac{1}{\theta'}+\frac{1}{\mu_k^{(N)'}}\right)^{-1}||\boldsymbol{\Delta}_i(t)|| & (153) \\ & \leq ||\boldsymbol{\Delta}_i(t)|| & (154) \end{aligned}$$

where $||\cdot||_2$ denotes the spectral norm of a matrix, which is defined as the largest eigenvalue of a matrix [22]. Therefore, the second term in (138) is bounded by

$$\begin{aligned}\left|\frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(\left(\frac{1}{\theta'}I+\Sigma_N'^{-1}\right)^{-1}\Sigma_N'^{-1}\boldsymbol{\Delta}_i(t)\right)_i dt\right| \\ &\le \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left|\left(\left(\frac{1}{\theta'}I+\Sigma_N'^{-1}\right)^{-1}\Sigma_N'^{-1}\boldsymbol{\Delta}_i(t)\right)_i\right| dt \quad (155)\\ &\le \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}||\boldsymbol{\Delta}_i(t)||dt \quad (156)\\ &= B^{(N)} \quad (157)\end{aligned}$$

where we have defined $B^{(N)}$ as

$$B^{(N)} = \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}||\boldsymbol{\Delta}_i(t)||dt \quad (158)$$

$$= \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left|\left|\boldsymbol{\rho}_N\left(\frac{i-1}{N-1}T_0\right)-\boldsymbol{\rho}_N(t)\right|\right| dt \quad (159)$$

Finally, the first term in (138) is bounded by

$$\begin{aligned}\frac{1}{T_0}\sum_{i=1}^{N-1}\left(\left(\frac{1}{\theta'}I+\Sigma_N'^{-1}\right)^{-1}\right)_{(i,i)} &\le \frac{1}{T_0}\sum_{i=1}^{N}\left(\left(\frac{1}{\theta'}I+\Sigma_N'^{-1}\right)^{-1}\right)_{(i,i)} \quad (160)\\ &= \frac{1}{T_0}\mathrm{tr}\left(\left(\frac{1}{\theta'}I+\Sigma_N'^{-1}\right)^{-1}\right) \quad (161)\\ &= \frac{1}{T_0}\sum_{k=0}^{N-1}\left(\frac{1}{\theta'}+\frac{1}{\mu_k'^{(N)}}\right)^{-1} \quad (162)\\ &\triangleq D_b^N(\theta') \quad (163)\end{aligned}$$

where the last step is by the definition of $D_b^N(\theta')$. Hence, for an arbitrary Gaussian random process, by (134), (138), (149), (150), (157) and (163), we have shown that

$$D_a^N(\theta') \le 2A^{(N)} + B^{(N)} + D_b^N(\theta') \quad (164)$$

9.7 Proof of Theorem 4

Each round of communication will take $2Nn$ time slots. In the $[2n(i-1)]$-th to $[2ni]$-th time slots, node i transmits at rate R_i, while all other nodes act as relay nodes and transmit no data of their own. In the end, the achievable sum rate is $\frac{\sum_{i=1}^N R_i}{N}$. We will show that each node can achieve $R_i = C_a^N$, and thus, all nodes can achieve the sum rate of C_a^N with identical individual rates.

We will consider the transmission of the data of node i. Node i codes its message using capacity achieving single-user coding techniques with codeword length n. Each codeword symbol requires two time slots. In the first time slot, node i transmits its codeword symbol using power $P(N)$. All other nodes remain silent, and receive a noisy version of node i's transmitted signal. The collector node ignores its received signal, which is suboptimal but eases calculation and does not affect the scaling law of the achievable rate. Identical individual power constraints of $P(N)/N$ for the nodes are satisfied, since all nodes take turns and node i will do this only $1/N$-th of the time, therefore its transmit power in $1/N$-th of the time is $P(N)$. In the second time slot, all sensor nodes, except node i, amplify and forward what they have received in the previous time slot to the collector node using an individual power constraint $P(N)/N$. The collector node, after $2n$ time slots, decodes using capacity achieving single-user decoding techniques. Now, we calculate the rate achievable with this scheme. In the first time slot, sensor node j receives

$$Y_j = h_{ij}X_i + Z_j, \qquad i,j = 1,2,\cdots,N, \quad j \neq i \tag{165}$$

and in the second time slot, sensor node j transmits

$$\begin{aligned} X_j &= \beta_{ij}Y_j && (166) \\ &= \beta_{ij}h_{ij}X_i + \beta_{ij}Z_j, \qquad i,j = 1,2,\cdots,N, \quad j \neq i && (167) \end{aligned}$$

where β_{ij} is the scaling coefficient of node j when it amplifies the signal it received from node i. In order to satisfy the identical individual power constraints, $\{\beta_{ij}\}_{j=1,j\neq i}^{N}$ have to satisfy

$$\beta_{ij}^2\left(h_{ij}^2 P(N) + 1\right) \leq \frac{P(N)}{N}, \qquad \forall i,j = 1,2,\cdots,N \tag{168}$$

The collector node receives

$$\begin{aligned} Y_0 &= \sum_{j=1,j\neq i}^{N} h_{j0}X_j + Z_0 && (169) \\ &= \left(\sum_{j=1,j\neq i}^{N} \beta_{ij}h_{ij}h_{j0}\right) X_i + \left(\sum_{j=1,j\neq i}^{N} h_{j0}\beta_{ij}Z_j\right) + Z_0 && (170) \end{aligned}$$

Therefore, the achievable rate is,

$$\frac{1}{4}\log\left(1 + \frac{\left(\sum_{j=1,j\neq i}^{N} \beta_{ij}h_{ij}h_{j0}\right)^2 P(N)}{\sum_{j=1,j\neq i}^{N} \left(\beta_{ij}h_{j0}\right)^2 + 1}\right) \tag{171}$$

where we have $\frac{1}{4}$ because we used two time slots to transmit one codeword symbol. We choose

$$\beta_{ij} = \zeta h_{ij} h_{j0} \tag{172}$$

where, in order to satisfy the power constraint, the constant ζ must satisfy

$$\zeta^2 \leq \frac{P(N)}{h_{ij}^4 h_{j0}^2 N P(N) + h_{ij}^2 h_{j0}^2 N}, \quad \forall i, j \tag{173}$$

We can choose ζ as

$$\zeta^2 = \frac{P(N)}{\bar{h}_u^6 N P(N) + \bar{h}_u^4 N} \tag{174}$$

Thus, from (171), an lower bound on the achievable rate is

$$\frac{1}{4} \log \left(1 + \frac{\zeta^2 \left(\sum_{j=1, j \neq i}^N h_{ij}^2 h_{j0}^2 \right)^2 P(N)}{\zeta^2 \left(\sum_{j=1, j \neq i}^N h_{ij}^2 h_{j0}^4 \right) + 1} \right) \geq \frac{1}{4} \log \left(1 + \frac{\bar{h}_l^8 \zeta^2 (N-1)^2 P(N)}{\bar{h}_u^6 \zeta^2 N + 1} \right) \triangleq C_b^N \tag{175}$$

Clearly, rate C_b^N can be achievable by any node i. We have

$$C_b^N = \frac{1}{4} \log \left(1 + \frac{\bar{h}_l^8 \left(P(N) \right)^2 \frac{(N-1)^2}{N}}{2 \bar{h}_u^6 P(N) + \bar{h}_u^4} \right) \tag{176}$$

$$\geq \frac{1}{4} \log \left(1 + \frac{\bar{h}_l^8 \left(P(N) \right)^2 N}{4 \bar{h}_u^6 P(N) + 2 \bar{h}_u^4} \right) \tag{177}$$

where the last step follows when N is large enough such that $\frac{(N-1)^2}{N} > \frac{N}{2}$.

When $P(N)$ is such that

$$\lim_{N \to \infty} \frac{1}{P(N)} = 0 \tag{178}$$

for any $0 < \kappa < 1$, we have,

$$C_b^N \geq \frac{1}{4} \log \left(1 + \frac{\bar{h}_l^8 \left(P(N) \right)^2 N}{8 \bar{h}_u^6 P(N)} \right) \tag{179}$$

$$= \frac{1}{4} \log \left(1 + \frac{\bar{h}_l^8}{8 \bar{h}_u^6} N P(N) \right) \tag{180}$$

$$\geq \frac{\kappa}{4} \log \left(N P(N) \right) \tag{181}$$

for N large enough, i.e., there exists $N_1(\kappa) > 0$, such that when $N > N_1(\kappa)$, (179) and (181) are true.

When $P(N)$ is such that

$$\lim_{N\to\infty} P(N) = l \tag{182}$$

and l is a number that satisfies $0 < l < \infty$, fix some small $l_0 > 0$, there exists an $N_2(l_0) > 0$ such that when $N > N_2(l_0)$, we have,

$$l - l_0 < P(N) < l + l_0 \tag{183}$$

Hence, when $N > N_2(l_0)$, for any $0 < \kappa < 1$,

$$\begin{aligned} C_b^N &\geq \frac{1}{4}\log\left(1 + \frac{\bar{h}_l^8(l-l_0)}{4\bar{h}_u^6(l+l_0) + 2\bar{h}_u^4}P(N)N\right) && (184)\\ &\geq \frac{\kappa}{4}\log\left(NP(N)\right) && (185)\end{aligned}$$

where the last step follows when N is large enough, i.e., when there exists an $N_3(\kappa) > 0$, such that when $N > \max\left(N_2(l_0), N_3(\kappa)\right)$, (185) is true.

When $P(N)$ is such that

$$\lim_{N\to\infty} P(N) = 0 \tag{186}$$

and there exists a constant $0 < \epsilon < \frac{1}{2}$, such that

$$\lim_{N\to\infty} P(N)N^{\frac{1}{2}-\epsilon} > 1 \tag{187}$$

we have, for $0 < \kappa < 1$,

$$\begin{aligned} C_b^N &\geq \frac{1}{4}\log\left(1 + \frac{\bar{h}_l^8}{4\bar{h}_u^4}(P(N))^2N\right) && (188)\\ &\geq \frac{\kappa}{4}\log\left((P(N))^2N\right) && (189)\\ &= \frac{\kappa}{4}\log(NP(N)) + \frac{\kappa}{4}\log(P(N)) && (190)\\ &\geq \frac{\kappa}{4}\frac{4\epsilon}{1+2\epsilon}\log(NP(N)) && (191)\end{aligned}$$

where the last step follows from

$$\frac{\kappa}{4}\left(1 - \frac{4\epsilon}{1+2\epsilon}\right)\log(NP(N)) + \frac{\kappa}{4}\log(P(N)) = \frac{\kappa}{4}\frac{2}{1+2\epsilon}\log(P(N)N^{\frac{1}{2}-\epsilon}) \geq 0 \tag{192}$$

when N is large enough, i.e., there exists an $N_4(\kappa) > 0$, such that when $N > N_4(\kappa)$, (188), (189) and (192) are true, and therefore, (191) is true.

Thus, combining all possible cases of $P(N)$, we see that when $P(N)$ is such that there exists a constant $\epsilon > 0$, such that

$$\lim_{N\to\infty} P(N)N^{\frac{1}{2}-\epsilon} > 1 \tag{193}$$

for any $0 < \kappa < 1$, the following rate C_a^N is achievable,

$$C_a^N = \kappa\nu \log(NP(N)) \tag{194}$$

where constant ν is

$$\nu = \min\left(\frac{\epsilon}{1+2\epsilon}, \frac{1}{4}\right) \tag{195}$$

when N is large enough.

Since all nodes take turns applying the same scheme, the individual rates of all sensors are the same, and the achievable sum rate is (194).

For all other $P(N)$, from (177), we see that the achievable sum rate approaches a positive constant or zero as N goes to infinity.

9.8 Proof of Lemma 3

We first consider $A^{(N)}$.

$$\begin{aligned}
A^{(N)} =& \frac{1}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(K(t,t) - K\left(\frac{i-1}{N-1}T_0, \frac{i-1}{N-1}T_0\right)\right)dt \\
&+ \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(\boldsymbol{\rho}_N\left(\frac{i-1}{N-1}T_0\right) - \boldsymbol{\rho}_N(t)\right)_i dt && (196)\\
\le& \frac{1}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left|K(t,t) - K\left(\frac{i-1}{N-1}T_0, \frac{i-1}{N-1}T_0\right)\right|dt \\
&+ \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left|\left(\boldsymbol{\rho}_N\left(\frac{i-1}{N-1}T_0\right) - \boldsymbol{\rho}_N(t)\right)_i\right| dt && (197)\\
\le& \frac{1}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0} B\left(\frac{\sqrt{2}}{N-1}T_0\right)^{\alpha} dt + \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0} B\left(\frac{1}{N-1}T_0\right)^{\alpha} dt && (198)\\
=& B\left(2^{\frac{\alpha}{2}}+2\right)T_0^{\alpha}\frac{1}{(N-1)^{\alpha}} && (199)\\
=& \Theta\left(N^{-\alpha}\right) && (200)
\end{aligned}$$

where (198) follows from condition 2 in Section 3. Using similar ideas, we have

$$
\begin{aligned}
B^{(N)} &= \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left\|\boldsymbol{\rho}_N\left(\frac{i-1}{N-1}T_0\right)-\boldsymbol{\rho}_N(t)\right\|dt && (201)\\
&= \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(\sum_{m=0}^{N-1}\left|K\left(\frac{i-1}{N-1}T_0,\frac{mT_0}{N-1}\right)-K\left(t,\frac{mT_0}{N-1}\right)\right|^2\right)^{\frac{1}{2}}dt && (202)\\
&\le \frac{2}{T_0}\sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left(\sum_{m=0}^{N-1}\left(B\left(\frac{T_0}{N-1}\right)^{\alpha}\right)^2\right)^{\frac{1}{2}}dt && (203)\\
&= 2BT_0^{\alpha}\frac{N^{\frac{1}{2}}}{(N-1)^{\alpha}} && (204)\\
&= \Theta\left(N^{\frac{1}{2}-\alpha}\right) && (205)
\end{aligned}
$$

9.9 Some properties of $\mu_k^{(N)'}$

Lemma 7 *For all Gaussian random processes in $\mathcal{A}$, let $K_1(N)$ be a sequence of numbers that satisfies*

$$
\begin{aligned}
\lim_{N\to\infty}\frac{1}{K_1(N)} &= 0 && (206)\\
\lim_{N\to\infty}\frac{\left(K_1(N)+B_4\right)^{2\tau}}{(N-1)^{\gamma}} &= 0 && (207)\\
\lim_{N\to\infty}\frac{K_1(N)^{x+1+\tau}}{(N-1)^{\beta}} &= 0 && (208)
\end{aligned}
$$

Then, for each k such that $k \le K_1(N)$, there exists an eigenvalue $\mu'^{(N)}$, different for each k, of Σ_N' such that

$$\left|\mu'^{(N)}-\lambda_k\right| \le d_1\frac{(k+B_7)^{\tau}}{(N-1)^{\beta}} \tag{209}$$

for some $d_1 > 0$ and some positive integer B_7, both independent of k and N, when N is large enough.

Lemma 7 shows that the convergence of $\mu_k^{(N)}$ to λ_k is not uniform, and the approximation of $\mu_k^{(N)}$ using λ_k is accurate only when $k << N^{\frac{\gamma}{\tau}}$ and $\lambda_k >> d_1\frac{(k+B_7)^{\tau}}{(N-1)^{\beta}}$. When the conditions of Lemma 7 are satisfied, we label the $\mu'^{(N)}$ that satisfies (209) to be $\mu_k^{(N)'}$ for $k \le K_1(N)$. The remaining $N-K_1(N)$ eigenvalues of $\mu'(N)$ will be labelled according to the order from large to small.

Lemma 8 *For all Gaussian random processes in* $\mathcal{A}$*, define two sequences* ϑ_L^N *and* ϑ_U^N *as*

$$\lim_{N\to\infty} \frac{1}{\vartheta_L^N N^{\min\left(\frac{x\gamma}{2\tau}, \frac{\alpha x}{x-1}, \frac{\beta x}{x+\tau+1}\right)}} = 0, \qquad \lim_{N\to\infty} \vartheta_U^N = 0 \tag{210}$$

For any constant $0 < \kappa < 1$*, we have*

$$\sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{N-1} \mu_k^{(N)'} \le \frac{d^{\frac{1}{x}}}{(x-1)\kappa^2} \theta'^{1-\frac{1}{x}} \tag{211}$$

when $\theta' \in [\vartheta_L^N, \vartheta_U^N]$ *and* N *is large enough.*

Lemma 8 shows that the sum of the eigenvalues that do not converge to λ_k for $k = 0, 1, \cdots, \left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor$ is quite small.

9.9.1 Proof of Lemma 7

By definition, λ_k for any k satisfies

$$\lambda_k \phi_k \left(\frac{l-1}{N-1} T_0\right) = \int_0^{T_0} K\left(\frac{l-1}{N-1} T_0, s\right) \phi_k(s) ds, \quad \forall l = 1, 2, \cdots, N \tag{212}$$

We rewrite the right hand side of (212) by

$$\frac{T_0}{N-1} \sum_{i=1}^{N} K\left(\frac{l-1}{N-1} T_0, \frac{i-1}{N-1} T_0\right) \phi_k\left(\frac{i-1}{N-1} T_0\right) + \epsilon_N^k\left(\frac{l-1}{N-1} T_0\right) \quad \forall l = 1, 2, \cdots, N \tag{213}$$

where $\epsilon_N^k\left(\frac{l-1}{N-1} T_0\right)$ is defined as

$$\begin{aligned} &\sum_{i=1}^{N-1} \int_{\frac{i-1}{N-1} T_0}^{\frac{i}{N-1} T_0} \left(K\left(\frac{l-1}{N-1} T_0, s\right) \phi_k(s) - K\left(\frac{l-1}{N-1} T_0, \frac{i-1}{N-1} T_0\right) \phi_k\left(\frac{i-1}{N-1} T_0\right)\right) ds \\ &- \frac{T_0}{N-1} K\left(\frac{l-1}{N-1} T_0, T_0\right) \phi_k(T_0) \end{aligned} \tag{214}$$

Using (212) and (213), we have for any $l = 1, 2, \cdots, N$,

$$\lambda_k \phi_k \left(\frac{l-1}{N-1} T_0\right) = \frac{T_0}{N-1} \sum_{i=1}^{N} K\left(\frac{l-1}{N-1} T_0, \frac{i-1}{N-1} T_0\right) \phi_k\left(\frac{i-1}{N-1} T_0\right) + \epsilon_N^k\left(\frac{l-1}{N-1} T_0\right) \tag{215}$$

i.e., we have

$$\lambda_k\sqrt{\frac{T_0}{N-1}}\phi_k\left(\frac{l-1}{N-1}T_0\right) = \frac{T_0}{N-1}\sum_{i=1}^{N} K\left(\frac{l-1}{N-1}T_0, \frac{i-1}{N-1}T_0\right)\sqrt{\frac{T_0}{N-1}}\phi_k\left(\frac{i-1}{N-1}T_0\right) \tag{216}$$

$$+\sqrt{\frac{T_0}{N-1}}\epsilon_N^k\left(\frac{l-1}{N-1}T_0\right) \tag{217}$$

Let us define vector $\mathbf{a}_k^{(N)}$ of length of N by defining its l-th element to be $\sqrt{\frac{T_0}{N-1}}\epsilon_N^k\left(\frac{l-1}{N-1}T_0\right)$ and vector $\mathbf{b}_k^{(N)}$ of length of N by defining its l-th element to be $\sqrt{\frac{T_0}{N-1}}\phi_k\left(\frac{l-1}{N-1}T_0\right)$, we have in matrix form

$$\lambda_k\mathbf{b}_k^{(N)} = \Sigma'_N\mathbf{b}_k^{(N)} + \mathbf{a}_k^{(N)} \tag{218}$$

The links between the eigenvalues of Σ'_N and the eigenvalues of $K(t,s)$, i.e., the λ_ks, will be determined using (218). To do this, we first bound three quantities, $\left|\left|\mathbf{a}_k^{(N)}\right|\right|$, $\left|\left|\mathbf{b}_k^{(N)}\right|\right|$, $\left|\mathbf{b}_m^{(N)^T}\mathbf{b}_l^{(N)}\right|$ for $k, m, l \leq K_1(N)$ and $m \neq l$.

We first upper bound $|\phi_k(T_0)|$. Let $F_k(s)$ be defined as

$$\int_0^s \phi_k^2(t)dt \tag{219}$$

Then, by the mean value theorem on interval $[0, T_0]$, we have that there exists a $T' \in [0, T_0]$, such that

$$1 = F_k(T_0) - F_k(0) = \phi_k^2(T') \tag{220}$$

Hence, using condition 3 in Section 3, we have

$$|\phi_k(t) - \phi_k(T')| \leq B_3(k+B_4)^\tau T_0^\gamma, \quad t \in [0, T_0] \tag{221}$$

Thus,

$$|\phi_k(t)| \leq B_3(k+B_4)^\tau T_0^\gamma + 1, \quad t \in [0, T_0] \tag{222}$$

Now, we analyze the norm of $\mathbf{a}_k^{(N)}$. From the definition of $\epsilon_N^k\left(\frac{l-1}{N-1}T_0\right)$ in (214), we have

$$\begin{aligned}
&\left|\epsilon_N^k\left(\frac{l-1}{N-1}T_0\right)\right| \\
&\leq \sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0}\left|K\left(\frac{l-1}{N-1}T_0, s\right)\phi_k(s) - K\left(\frac{l-1}{N-1}T_0, \frac{i-1}{N-1}T_0\right)\phi_k\left(\frac{i-1}{N-1}T_0\right)\right| ds \\
&\quad + \frac{T_0}{N-1}\left|K\left(\frac{l-1}{N-1}T_0, T_0\right)\right|\left|\phi_k(T_0)\right| && (223)\\
&\leq B_2 T_0^{1+\beta}\frac{(k+B_1)^\tau}{(N-1)^\beta} + \frac{T_0\bar{K}(T_0)\left|\phi_k(T_0)\right|}{N-1} && (224)\\
&\leq B_2 T_0^{1+\beta}\frac{(k+B_1)^\tau}{(N-1)^\beta} + \frac{T_0\bar{K}(T_0)\left(B_3(k+B_4)^\tau T_0^\gamma + 1\right)}{N-1} && (225)\\
&\leq B_2 T_0^{1+\beta}\frac{(k+B_1)^\tau}{(N-1)^\beta} + \frac{T_0\bar{K}(T_0)\left(B_3(k+B_4)^\tau T_0^\gamma + 1\right)}{(N-1)^\beta} && (226)\\
&\leq \frac{\left(B_2 T_0^{1+\beta} + T_0^{1+\gamma}\bar{K}(T_0)B_3\right)(k+\max(B_1,B_4))^\tau + T_0\bar{K}(T_0)}{(N-1)^\beta} && (227)\\
&\leq \frac{\max\left(1, \left(B_2 T_0^{1+\beta} + T_0^{1+\gamma}\bar{K}(T_0)B_3\right)\right)\left((k+\max(B_1,B_4))^\tau + \left(\left(T_0\bar{K}(T_0)\right)^{1/\tau}\right)^\tau\right)}{(N-1)^\beta} && (228)\\
&\leq \frac{\max\left(1, 2^{1-\tau}\right)\max\left(1, \left(B_2 T_0^{1+\beta} + T_0^{1+\gamma}\bar{K}(T_0)B_3\right)\right)\left(k+\max(B_1,B_4) + \left(T_0\bar{K}(T_0)\right)^{1/\tau}\right)^\tau}{(N-1)^\beta} && (229)\\
&\leq B_6\frac{(k+B_7')^\tau}{(N-1)^\beta} && (230)
\end{aligned}$$

where (224) follows because the random process satisfies condition 3 in Section 3, and because $\bar{K}(T_0)$ is defined as

$$\max_{1\leq l\leq N}\left|K\left(\frac{l-1}{N-1}T_0, T_0\right)\right| \tag{231}$$

and is a finite nonnegative number since $K(t,s)$ satisfies condition 2 in Section 3 and thus, is continuous, (225) follows from (222), and (226) follows because $\beta \leq 1$ from condition 3 in Section 3, and (229) follows because for $\forall u, v > 0$

$$u^\tau + v^\tau \leq (u+v)^\tau, \quad \tau \geq 1 \tag{232}$$

$$\frac{u^\tau + v^\tau}{2} \leq \left(\frac{u+v}{2}\right)^\tau, \quad 0 \leq \tau < 1 \tag{233}$$

(230) comes because we define the variables B_6 and B_7', which are both independent of k

and N, as

$$B_6 = \max\left(1, 2^{1-\tau}\right) \max\left(1, \left(B_2 T_0^{1+\beta} + T_0^{1+\gamma} \bar{K}(T_0) B_3\right)\right) \tag{234}$$

$$B_7' = \left\lceil \max(B_1, B_4) + \left(T_0 \bar{K}(T_0)\right)^{1/\tau} \right\rceil \tag{235}$$

Note that B_7' is a positive integer. Finally, we calculate the norm of vector $\mathbf{a}_k^{(N)}$ as

$$\left\|\mathbf{a}_k^{(N)}\right\| = \sqrt{\sum_{l=1}^{N} \left(\sqrt{\frac{T_0}{N-1}} \epsilon_k^N \left(\frac{l-1}{N-1} T_0\right)\right)^2} \tag{236}$$

$$\leq \sqrt{\frac{N T_0}{N-1}} B_6 \frac{(k + B_7')^\tau}{(N-1)^\beta} \tag{237}$$

$$\leq 2 B_6 \sqrt{T_0} \frac{(k + B_7')^\tau}{(N-1)^\beta} \tag{238}$$

where (238) follows when N is large enough, more specifically, there exists an interger N_1 such that when $N > N_1$, we have $\sqrt{\frac{N}{N-1}} \leq 2$.

Now, we will calculate the norm of vector $\mathbf{b}_k^{(N)}$. We write

$$1 = \int_0^{T_0} \phi_k^2(s) ds = \sum_{i=1}^{N} \frac{T_0}{N-1} \phi_k^2 \left(\frac{i-1}{N-1} T_0\right) + \delta_N^k \tag{239}$$

where δ_N^k is defined as

$$\delta_N^k = \sum_{i=1}^{N-1} \int_{\frac{i-1}{N-1} T_0}^{\frac{i}{N-1} T_0} \left(\phi_k^2(s) - \phi_k^2 \left(\frac{i-1}{N-1} T_0\right)\right) ds - \frac{T_0}{N-1} \phi_k^2(T_0) \tag{240}$$

Using (14), we have for any $s_1, s_2 \in [0, T_0]$,

$$\left|\phi_k^2(s_1) - \phi_k^2(s_2)\right| = \left|\phi_k(s_1) + \phi_k(s_2)\right| \left|\phi_k(s_1) - \phi_k(s_2)\right| \tag{241}$$

$$\leq 2 \max_{s \in [0, T_0]} \left|\phi_k(s)\right| B_3 (k + B_4)^\tau \left|s_1 - s_2\right|^\gamma \tag{242}$$

$$\leq 2 \left(B_3 (k + B_4)^\tau T_0^\gamma + 1\right) B_3 (k + B_4)^\tau \left|s_1 - s_2\right|^\gamma \tag{243}$$

where (243) follows from (222). The approximation error, δ_N^k satisfies

$$|\delta_N^k| \le \sum_{i=1}^{N-1} \int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0} \left| \phi_k^2(s) - \phi_k^2\left(\frac{i-1}{N-1}T_0\right) \right| ds + \frac{T_0 \phi_k^2(T_0)}{N-1} \tag{244}$$

$$\le T_0^{1+\gamma} \frac{2\left(B_3(k+B_4)^\tau T_0^\gamma + 1\right) B_3(k+B_4)^\tau}{(N-1)^\gamma} + \frac{T_0 \phi_k^2(T_0)}{N-1} \tag{245}$$

$$\le T_0^{1+\gamma} \frac{2\left(B_3(k+B_4)^\tau T_0^\gamma + 1\right) B_3(k+B_4)^\tau}{(N-1)^\gamma} + \frac{T_0\left(B_3(k+B_4)^\tau T_0^\gamma + 1\right)^2}{N-1} \tag{246}$$

$$\le T_0^{1+\gamma} \frac{2\left(B_3(k+B_4)^\tau T_0^\gamma + 1\right) B_3(k+B_4)^\tau}{(N-1)^\gamma} + \frac{T_0\left(B_3(k+B_4)^\tau T_0^\gamma + 1\right)^2}{(N-1)^\gamma} \tag{247}$$

$$\le \frac{3T_0^{1+2\gamma} B_3^2 (k+B_4)^{2\tau} + 4T_0^{1+\gamma} B_3 (k+B_4)^\tau}{(N-1)^\gamma} + \frac{T_0}{(N-1)^\gamma} \tag{248}$$

where (246) follows from (222), and (247) follows from the condition of $\gamma \le 1$ in condition 3 in Section 3. Due to the fact that $K_1(N)$ satisfies (206) and (207), for a fixed constant B_5 that satisfies $0 < B_5 < 1$, Then, there exists an integer $N_0 > 0$, such that for $N \ge N_0$,

$$\frac{3T_0^{1+2\gamma} B_3^2 (K_1(N)+B_4)^{2\tau} + 4T_0^{1+\gamma} B_3 (K_1(N)+B_4)^\tau}{(N-1)^\gamma} + \frac{T_0}{(N-1)^\gamma} \le B_5 \tag{249}$$

Hence, for any $k \le K_1(N)$ and $N \ge N_0$, we have

$$|\delta_N^k| \le \frac{3T_0^{1+2\gamma} B_3^2 (k+B_4)^{2\tau} + 4T_0^{1+\gamma} B_3 (k+B_4)^\tau}{(N-1)^\gamma} + \frac{T_0}{(N-1)^\gamma} \tag{250}$$

$$\le \frac{3T_0^{1+2\gamma} B_3^2 (K_1(N)+B_4)^{2\tau} + 4T_0^{1+\gamma} B_3 (K_1(N)+B_4)^\tau}{(N-1)^\gamma} + \frac{T_0}{(N-1)^\gamma} \tag{251}$$

$$\le B_5 \tag{252}$$

Finally, by the definition of $\mathbf{b}_k^{(N)}$, we have

$$\left|\left|\mathbf{b}_k^{(N)}\right|\right| = \sqrt{\sum_{i=1}^{N} \frac{T_0}{N-1} \phi_k^2\left(\frac{i-1}{N-1}T_0\right)} \tag{253}$$

$$= \sqrt{1 - \delta_N^k} \tag{254}$$

$$\ge \sqrt{1 - \left|\delta_N^k\right|} \tag{255}$$

$$\ge \sqrt{1 - B_5} \tag{256}$$

where (254) follows from (239). Similarly, we have

$$\left|\left|\mathbf{b}_k^{(N)}\right|\right| \le \sqrt{1 + B_5} \tag{257}$$

Next, we show that based on the orthogonality of the eigenfunctions of $\phi_k(t)$, the sampled version $\mathbf{b}_k^{(N)}$s are almost orthogonal. Using (14), we have

$$\begin{aligned}
&|\phi_m(s_1)\phi_l(s_1) - \phi_m(s_2)\phi_l(s_2)| && (258)\\
&= |\phi_m(s_1)\phi_l(s_1) - \phi_m(s_1)\phi_l(s_2) + \phi_m(s_1)\phi_l(s_2) - \phi_m(s_2)\phi_l(s_2)| && (259)\\
&\leq |\phi_m(s_1)\phi_l(s_1) - \phi_m(s_1)\phi_l(s_2)| + |\phi_m(s_1)\phi_l(s_2) - \phi_m(s_2)\phi_l(s_2)| && (260)\\
&\leq \max_{s_1\in[0,T_0]} |\phi_m(s_1)|\,|\phi_l(s_1) - \phi_l(s_2)| + \max_{s_2\in[0,T_0]} |\phi_l(s_2)|\,|\phi_m(s_1) - \phi_m(s_2)| && (261)\\
&\leq \left(B_3(m+B_4)^\tau T_0^\gamma + 1\right) B_3(l+B_4)^\tau |s_1-s_2|^\gamma + \left(B_3(l+B_4)^\tau T_0^\gamma + 1\right) B_3(m+B_4)^\tau |s_1-s_2|^\gamma && (262)\\
&= \left(2B_3^2(m+B_4)^\tau(l+B_4)^\tau T_0^\gamma + B_3(l+B_4)^\tau + B_3(m+B_4)^\tau\right)|s_1-s_2|^\gamma && (263)
\end{aligned}$$

where (262) follows from (222). Let m and l be two different integers, that belong to $\{1, 2, \cdots, N\}$. Then, we have

$$0 = \int_0^{T_0} \phi_m(t)\phi_l(t)dt = \sum_{i=1}^{N} \frac{T_0}{N-1}\phi_m\left(\frac{i-1}{N-1}T_0\right)\phi_l\left(\frac{i-1}{N-1}T_0\right) + \varepsilon_N^{m,l} \qquad (264)$$

Then, we have

$$\begin{aligned}
\left|\varepsilon_N^{m,l}\right| =& \left|\int_0^{T_0} \phi_m(t)\phi_l(t)dt - \sum_{i=1}^{N} \frac{T_0}{N-1}\phi_m\left(\frac{i-1}{N-1}T_0\right)\phi_l\left(\frac{i-1}{N-1}T_0\right)\right| && (265)\\
\leq& \sum_{i=1}^{N-1}\int_{\frac{i-1}{N-1}T_0}^{\frac{i}{N-1}T_0} \left|\phi_m(t)\phi_l(t) - \phi_m\left(\frac{i-1}{N-1}T_0\right)\phi_l\left(\frac{i-1}{N-1}T_0\right)\right| dt\\
&+ \frac{T_0}{N-1}|\phi_m(T_0)|\,|\phi_l(T_0)| && (266)\\
\leq& T_0^{1+\gamma}\frac{2B_3^2(m+B_4)^\tau(l+B_4)^\tau T_0^\gamma + B_3(l+B_4)^\tau + B_3(m+B_4)^\tau}{(N-1)^\gamma} && (267)\\
&+ T_0\frac{\left(B_3(m+B_4)^\tau T_0^\gamma + 1\right)\left(B_3(l+B_4)^\tau T_0^\gamma + 1\right)}{N-1} && (268)\\
\leq& T_0^{1+\gamma}\frac{2B_3^2(m+B_4)^\tau(l+B_4)^\tau T_0^\gamma + B_3(l+B_4)^\tau + B_3(m+B_4)^\tau}{(N-1)^\gamma} && (269)\\
&+ T_0\frac{\left(B_3(m+B_4)^\tau T_0^\gamma + 1\right)\left(B_3(l+B_4)^\tau T_0^\gamma + 1\right)}{(N-1)^\gamma} && (270)\\
=& \frac{3B_3^2(m+B_4)^\tau(l+B_4)^\tau T_0^{1+2\gamma} + 2B_3(l+B_4)^\tau T_0^{1+\gamma} + 2B_3(m+B_4)^\tau T_0^{1+\gamma} + T_0}{(N-1)^\gamma} && (271)
\end{aligned}$$

For $m, l \leq K_1(N)$, we have

$$\left|\varepsilon_N^{m,l}\right| \leq \frac{3B_3^2(K_1(N)+B_4)^{2\tau}T_0^{1+2\gamma} + 4B_3(K_1(N)+B_4)^{\tau}T_0^{1+\gamma} + T_0}{(N-1)^{\gamma}} \tag{272}$$

$$\leq \frac{4B_3^2(K_1(N)+B_4)^{2\tau}T_0^{1+2\gamma}}{(N-1)^{\gamma}} \tag{273}$$

where (273) follows when N is large enough due to the fact that $K_1(N)$ satisfies (206), i.e., there exists an integer N_2 such that when $N > N_2$, (273) is true. The right hand side of (273) converges to zero as N goes to infinity due to the fact that $K_1(N)$ satisfies (207). We have

$$\left|\mathbf{b}_m^{(N)^T}\mathbf{b}_l^{(N)}\right| = \left|\sum_{i=1}^{N}\frac{T_0}{N-1}\phi_m\left(\frac{i-1}{N-1}T_0\right)\phi_l\left(\frac{i-1}{N-1}T_0\right)\right| = \left|\varepsilon_N^{m,l}\right| \tag{274}$$

$$\leq \frac{4B_3^2(K_1(N)+B_4)^{2\tau}T_0^{1+2\gamma}}{(N-1)^{\gamma}} \tag{275}$$

which means that vectors $\mathbf{b}_m^{(N)}$ and $\mathbf{b}_l^{(N)}$ become more orthogonal as N gets larger.

Now, we are ready to establish the link between the eigenvalues of Σ_N' and λ_k. From (218), we have

$$\mathbf{b}_k^{(N)} = \left(\Sigma_N' - \lambda_k I\right)^{-1}\left(-\mathbf{a}_k^{(N)}\right) \tag{276}$$

Hence,

$$\left\|\mathbf{b}_k^{(N)}\right\| \leq \left\|\left(\Sigma_N' - \lambda_k I\right)^{-1}\right\|_2 \left\|\mathbf{a}_k^{(N)}\right\| \tag{277}$$

$$= \left(\min_{0\leq m\leq N-1}\left(\mu_m^{(N)'} - \lambda_k\right)\right)^{-1}\left\|\mathbf{a}_k^{(N)}\right\| \tag{278}$$

Thus, we have

$$\min_{0\leq m\leq N-1}\left(\mu_m^{(N)'} - \lambda_k\right) \leq \frac{\left\|\mathbf{a}_k^{(N)}\right\|}{\left\|\mathbf{b}_k^{(N)}\right\|} \tag{279}$$

$$\leq \frac{2B_6\sqrt{T_0}\frac{(k+B_7')^{\tau}}{(N-1)^{\beta}}}{\sqrt{1-B_5}} \tag{280}$$

$$\leq d_0\frac{(k+B_7')^{\tau}}{(N-1)^{\beta}} \tag{281}$$

where (281) follows by defining d_0 as

$$d_0 = \frac{2B_6\sqrt{T_0}}{\sqrt{1-B_5}} \tag{282}$$

Hence, for $k = 0, 1, 2, \cdots, K_1(N)$, there exists an eigenvalue $\mu'^{(N)}$ of Σ'_N such that

$$\left|\mu'^{(N)} - \lambda_k\right| \le d_0 \frac{(k+B'_7)^\tau}{(N-1)^\beta} \tag{283}$$

when N is large enough, more specifically, when $N \ge \max(N_0, N_1, N_2)$.

For $k = 0, 1, 2, \cdots, K_1(N)$, if we label the $\mu'^{(N)}$ that satisfies (283) to be $\mu_k^{(N)'}$, then when λ_k for different ks are sufficiently close, more specifically,

$$|\lambda_m - \lambda_l| \le 2d_0 \frac{(K_1(N)+B'_7)^\tau}{(N-1)^\beta}, \quad m, l \le K_1(N), m \ne l \tag{284}$$

$\mu_m^{(N)'}$ and $\mu_l^{(N)'}$ might correspond to the same eigenvalue of Σ'_N, which is undesirable. If we relax the minimum distance of $d_0 \frac{(k+B'_7)^\tau}{(N-1)^\beta}$, we will be able to eliminate this problem. Thus, we will next show that for $k = 0, 1, 2, \cdots, K_1(N)$, there exists an eigenvalue $\mu'^{(N)}$ of Σ'_N, different for each k, such that

$$\left|\mu'^{(N)} - \lambda_k\right| \le (2\bar{\chi}+1)\sqrt{d_2}\, d_0 \frac{(k+\bar{\chi}+B'_7)^\tau}{(N-1)^\beta} \tag{285}$$

when N is large enough, where we define $\bar{\chi} \overset{\triangle}{=} \max(K_0+1+c_u+c_l, 2c_u+2c_l+1)$ and constant d_2 as the largest root of the following second-order equation

$$(1-B_5)d_2^2 - 2\left((1-B_5) + 3\bar{\chi}(1+B_5)\right)d_2 + (1-B_5) + 2\bar{\chi}(1+B_5) = 0 \tag{286}$$

It can be checked that both roots of the above equation are real, and the largest root is a positive constant, strictly larger than $\frac{2\bar{\chi}(1+B_5)}{1-B_5} + 1$, that is a function of $\bar{\chi}$ and B_5.

First, let us define a cluster of λs. We say that χ λs are a cluster, where with no loss of generality, we may label these λs $\lambda_k, \lambda_{k+1}, \cdots, \lambda_{k+\chi-1}$, if

$$\lambda_{k+l} - \lambda_{k+l+1} \le 2\sqrt{d_2}\, d_0 \frac{(k+\bar{\chi}+B'_7)^\tau}{(N-1)^\beta}, \quad l = 0, 1, \cdots, \chi-1 \tag{287}$$

Note here that whether the λs are in a cluster depends on N.

Next, we prove that the number of λs within a cluster is upper bounded by $\bar{\chi}$ when N is large enough. For $k > K_0$, we have

$$\frac{d}{(k+c_l)^x} \le \lambda_k \le \frac{d}{(k-c_u)^x} \tag{288}$$

$$\frac{d}{(k+2c_l+c_u+1)^x} \le \lambda_{k+c_u+c_l+1} \le \frac{d}{(k+c_l+1)^x} \tag{289}$$

Hence, for every $k \ge K_0$, the distance between λ_k and $\lambda_{k+c_u+c_l+1}$ satisfies

$$\lambda_k - \lambda_{k+c_u+c_l+1} \ge \frac{d}{(k+c_l)^x} - \frac{d}{(k+c_l+1)^x} \tag{290}$$

which is a non-increasing function of k. Thus, for all $K_0 < k \le K_1(N)$, the distance between λ_k and $\lambda_{k+c_u+c_l+1}$ satisfies

$$\begin{aligned}
\lambda_k - \lambda_{k+c_u+c_l+1} &\ge \frac{d}{(K_1(N)+c_l)^x} - \frac{d}{(K_1(N)+c_l+1)^x} && (291)\\
&= \frac{d}{(K_1(N)+c_l)^x}\left(1-\left(1-\frac{1}{K_1(N)+c_l+1}\right)^x\right) && (292)\\
&\ge \frac{d}{(K_1(N)+c_l)^x}\left(x\frac{1}{K_1(N)+c_l+1} - \frac{x(x-1)}{2}\frac{1}{(K_1(N)+c_l+1)^2}\right) && (293)\\
&= \frac{xd}{(K_1(N)+c_l)^{x+1}} - \frac{x(x-1)d}{2(K_1(N)+c_l)^{x+2}} && (294)\\
&\ge \frac{xd}{2(K_1(N)+c_l)^{x+1}} && (295)\\
&> 2\sqrt{d_2}d_0\frac{(K_1(N)+\bar{\chi}+B'_7)^\tau}{(N-1)^\beta} && (296)
\end{aligned}$$

where (295) is true when N is large enough due to the fact that $K_1(N)$ satisfies (206), i.e., there exists an integer N_3, such that when $N > N_3$, (295) is true, and (296) is true when N is large enough, due to the fact that $K_1(N)$ satisfies (208), i.e., there exists an integer N_4, such that when $N > N_4$, (296) is true.

Hence, for all $K_0 < k \le K_1(N)$, when N is large enough, more specifically, when $N > \max(N_3, N_4)$, due to the sufficient distance between λ_k and $\lambda_{k+c_u+c_l+1}$, shown in (296), they cannot be in the same cluster. Hence, we may conclude that for large enough N, the size of a cluster is at most $\bar{\chi}$, which is a finite number.

Following from (218), we have

$$\left(\lambda_k I - \Sigma'_N\right)\mathbf{b}_k^{(N)} = \mathbf{a}_k^{(N)} \tag{297}$$

Let the eigenvalues and the corresponding eigenvectors of Σ'_N be $\mu_i^{(N)'}$ and $\mathbf{u}_i^{(N)}$, $i =$

$1, 2, \cdots, N$, with arbitrary labelling of the eigenvalues and eigenvectors. Then we have

$$\sum_{i=1}^{N} \left(\lambda_k - \mu_i^{(N)'}\right) \mathbf{u}_i^{(N)} \mathbf{u}_i^{(N)^T} \mathbf{b}_k^{(N)} = \mathbf{a}_k^{(N)} \tag{298}$$

We take the norm squared on both sides, and due to the orthogonality of eigenvectors $\mathbf{u}_i^{(N)}$, we have

$$\sum_{i=1}^{N} \left(\lambda_k - \mu_i^{(N)'}\right)^2 \left(\mathbf{u}_i^{(N)^T} \mathbf{b}_k^{(N)}\right)^2 = \left|\left|\mathbf{a}_k^{(N)}\right|\right|^2, \quad k = 0, 1, 2, \cdots \tag{299}$$

and we also have

$$\sum_{i=1}^{N} \left(\mathbf{u}_i^{(N)^T} \mathbf{b}_k^{(N)}\right)^2 = \left|\left|\mathbf{b}_k^{(N)}\right|\right|^2, \quad k = 0, 1, 2, \cdots \tag{300}$$

Let $\lambda_k, \lambda_{k+1}, \cdots, \lambda_{k+\chi-1}$ be a cluster, and from previous arguments, we know $\chi \leq \bar{\chi}$. Furthermore, we are only interested in the first $K_1(N) + 1$ eigenvalues, and therefore $k + \chi - 1 \leq K_1(N)$. We will prove by contradiction. Suppose that only ς number of $\mu_i^{(N)'}$s are within distance

$$\sqrt{d_2} d_0 \frac{(k + \bar{\chi} + B_7')^\tau}{(N-1)^\beta} \tag{301}$$

from any of the $\lambda_k, \lambda_{k+1}, \cdots, \lambda_{k+\chi-1}$, with $1 \leq \varsigma < \chi$, we will show that there is a contradiction, and therefore, we can conclude that our assumption that $\varsigma < \chi$ number of $\mu_i^{(N)'}$s are within distance (301) from any of the $\lambda_k, \lambda_{k+1}, \cdots, \lambda_{k+\chi}$ is not correct. Note that $\varsigma \geq 1$ because we have already proved (283). Based on (281), the distance in (301) satisfies

$$\sqrt{d_2} d_0 \frac{(k + \bar{\chi} + B_7')^\tau}{(N-1)^\beta} \geq \frac{\sqrt{d_2} ||\mathbf{a}_{k+l}^{(N)}||}{||\mathbf{b}_{k+l}^{(N)}||}, \quad l = 0, 1, \cdots, \chi - 1 \tag{302}$$

Then, based on (299), we have

$$\left(\frac{\sqrt{d_2} ||\mathbf{a}_{k+l}^{(N)}||}{||\mathbf{b}_{k+l}^{(N)}||}\right)^2 \sum_{i=\varsigma+1}^{N} \left(\mathbf{u}_i^{(N)^T} \mathbf{b}_{k+l}^{(N)}\right)^2 \leq \left|\left|\mathbf{a}_{k+l}^{(N)}\right|\right|^2, \quad l = 0, 1, \cdots, \chi - 1 \tag{303}$$

where we have labelled the $\mu'^{(N)}$ that are within distance (301) from any of the $\lambda_k, \lambda_{k+1}, \cdots, \lambda_{k+\chi}$

$\mu_1^{(N)'}, \mu_2^{(N)'}, \cdots, \mu_\varsigma^{(N)'}$. Hence, we have

$$\sum_{i=\varsigma+1}^{N} \left(\mathbf{u}_i^{(N)^T} \mathbf{b}_{k+l}^{(N)}\right)^2 \leq \frac{||\mathbf{b}_{k+l}^{(N)}||^2}{d_2}, \quad l = 0, 1, \cdots, \chi - 1 \tag{304}$$

Together with (300), we have

$$\sum_{i=1}^{\varsigma} \left(\mathbf{u}_i^{(N)^T} \mathbf{b}_{k+l}^{(N)}\right)^2 \geq \frac{(d_2 - 1)||\mathbf{b}_{k+l}^{(N)}||^2}{d_2}, \quad l = 0, 1, \cdots, \chi - 1 \tag{305}$$

Since the $\mathbf{u}_i^{(N)}$ form a complete set of basis in $\mathbb{R}^N$, we can write $\mathbf{b}_{k+l}^{(N)}$ as

$$\mathbf{b}_{k+l}^{(N)} = \sum_{i=1}^{\varsigma} \alpha_{k+l,i} \mathbf{u}_i^{(N)} + \mathbf{v}_{k+l}^{(N)}, \quad l = 0, 1, \cdots, \chi - 1 \tag{306}$$

where $\mathbf{v}_{k+l}^{(N)}$ is orthogonal to $\mathbf{u}_i^{(N)}$, for $i = 1, 2, \cdots, \varsigma$. If we take the expression of $\mathbf{b}_{k+l}^{(N)}$ in (306) and plug it in (305), we get

$$\sum_{i=1}^{\varsigma} (\alpha_{k+l,i})^2 \geq \frac{(d_2 - 1)||\mathbf{b}_{k+l}^{(N)}||^2}{d_2}, \quad l = 0, 1, 2, \cdots, \chi - 1 \tag{307}$$

From (306), we get

$$||\mathbf{b}_{k+l}^{(N)}||^2 = \sum_{i=1}^{\varsigma} (\alpha_{k+l,i})^2 + ||\mathbf{v}_{k+l}^{(N)}||^2, \quad l = 0, 1, \cdots, \varsigma - 1 \tag{308}$$

Hence, we conclude that

$$||\mathbf{v}_{k+l}^{(N)}||^2 \leq \frac{||\mathbf{b}_{k+l}^{(N)}||^2}{d_2}, \quad l = 0, 1, \cdots, \varsigma - 1 \tag{309}$$

Furthermore, from (306), we have

$$\mathbf{b}_{k+m}^{(N)^T} \mathbf{b}_{k+l}^{(N)} = \sum_{i=1}^{\varsigma} \alpha_{k+m,i} \alpha_{k+l,i} + \mathbf{v}_{k+m}^{(N)^T} \mathbf{v}_{k+l}^{(N)}, \quad m, l = 0, 1, \cdots, \varsigma - 1, m \neq l \tag{310}$$

Hence, we have

$$\sum_{i=1}^{\varsigma} \alpha_{k+m,i} \alpha_{k+l,i} = \mathbf{b}_{k+m}^{(N)^T} \mathbf{b}_{k+l}^{(N)} - \mathbf{v}_{k+m}^{(N)^T} \mathbf{v}_{k+l}^{(N)}, \quad m, l = 0, 1, \cdots, \varsigma - 1, m \neq l \tag{311}$$

and for $m, l = 0, 1, \cdots, \varsigma - 1, m \neq l$, we have

$$\left|\sum_{i=1}^{\varsigma} \alpha_{k+m,i}\alpha_{k+l,i}\right| \leq \left|\mathbf{b}_{k+m}^{(N)^T}\mathbf{b}_{k+l}^{(N)}\right| + \left|\mathbf{v}_{k+m}^{(N)^T}\mathbf{v}_{k+l}^{(N)}\right| \tag{312}$$

$$\leq \frac{4B_3^2(K_1(N)+B_4)^{2\tau}T_0^{1+2\gamma}}{(N-1)^\gamma} + \left\|\mathbf{v}_{k+m}^{(N)^T}\right\|\left\|\mathbf{v}_{k+l}^{(N)}\right\| \tag{313}$$

$$\leq \frac{4B_3^2(K_1(N)+B_4)^{2\tau}T_0^{1+2\gamma}}{(N-1)^\gamma} + \frac{\left\|\mathbf{b}_{k+m}^{(N)^T}\right\|\left\|\mathbf{b}_{k+l}^{(N)}\right\|}{d_2} \tag{314}$$

$$\leq \frac{4B_3^2(K_1(N)+B_4)^{2\tau}T_0^{1+2\gamma}}{(N-1)^\gamma} + \frac{1+B_5}{d_2} \tag{315}$$

$$\leq \frac{2(1+B_5)}{d_2} \tag{316}$$

where (313) follows from (275) when $N > N_2$, (314) follows from (309), (315) follows from (257) when $N > N_0$, and (316) follows when N is large enough, due to the fact that $K_1(N)$ satisfies (207), i.e., there exists an integer N_6, when $N > N_6$, (316) is true. Let us define matrix A to be

$$A = \begin{bmatrix} \alpha_{k,1} & \alpha_{k,2} & \cdots & \alpha_{k,\varsigma} \\ \alpha_{k+1,1} & \alpha_{k+1,2} & \cdots & \alpha_{k+1,\varsigma} \\ \vdots & \vdots & \ddots & \vdots \\ \alpha_{k+\varsigma-1,1} & \alpha_{k+\varsigma-1,2} & \cdots & \alpha_{k+\varsigma-1,\varsigma} \end{bmatrix} \tag{317}$$

and define vectors $\mathbf{b}$, $\mathbf{v}$, $\mathbf{u}$ to be

$$\mathbf{b} = \begin{bmatrix} \mathbf{b}_k^{(N)^T}\mathbf{b}_{k+\varsigma}^{(N)} \\ \mathbf{b}_{k+1}^{(N)^T}\mathbf{b}_{k+\varsigma}^{(N)} \\ \vdots \\ \mathbf{b}_{k+\varsigma-1}^{(N)^T}\mathbf{b}_{k+\varsigma}^{(N)} \end{bmatrix}, \quad \mathbf{v} = \begin{bmatrix} \mathbf{v}_k^{(N)^T}\mathbf{b}_{k+\varsigma}^{(N)} \\ \mathbf{v}_{k+1}^{(N)^T}\mathbf{b}_{k+\varsigma}^{(N)} \\ \vdots \\ \mathbf{v}_{k+\varsigma-1}^{(N)^T}\mathbf{b}_{k+\varsigma}^{(N)} \end{bmatrix}, \quad \mathbf{u} = \begin{bmatrix} \mathbf{u}_1^{(N)^T}\mathbf{b}_{k+\varsigma}^{(N)} \\ \mathbf{u}_2^{(N)^T}\mathbf{b}_{k+\varsigma}^{(N)} \\ \vdots \\ \mathbf{u}_\varsigma^{(N)^T}\mathbf{b}_{k+\varsigma}^{(N)} \end{bmatrix} \tag{318}$$

Then, by (306), we have

$$\mathbf{b} = A\mathbf{u} + \mathbf{v} \tag{319}$$

In other words,

$$\mathbf{u} = A^{-1}(\mathbf{b} - \mathbf{v}) \tag{320}$$

thus, we have

$$||\mathbf{u}||^2 = \left|\left|A^{-1}\right|\right|_2^2 (||\mathbf{b}|| + ||\mathbf{v}||)^2 \tag{321}$$

We start by evaluating $||A^{-1}||_2^2$, which is equal to the inverse of the smallest eigenvalue of $A^T A$. From the definition of matrix A in (317), we have

$$A^T A = D + E \tag{322}$$

where D is an $\varsigma \times \varsigma$ diagonal matrix with the l-th diagonal element being $\sum_{i=1}^{\varsigma} (\alpha_{k+l-1,i})^2$, and E is an $\varsigma \times \varsigma$ matrix with zero diagonals and (m, l)-th element being $\sum_{i=1}^{\varsigma} \alpha_{k+m-1,i}\alpha_{k+l-1,i}$, when $m \neq l$. The absolute difference between the smallest eigenvalue of $A^T A$ and D is upper bounded by $||E||_2$ [23]. The smallest eigenvalue of D is

$$\min_{l \in \{0,1,\cdots,\varsigma-1\}} \sum_{i=1}^{\varsigma} (\alpha_{k+l,i})^2 \geq \min_l \frac{(d_2 - 1)||\mathbf{b}_{k+l}^{(N)}||^2}{d_2} \tag{323}$$

$$\geq \frac{(d_2 - 1)(1 - B_5)}{d_2} \tag{324}$$

where (323) follows from (307), and (324) follows from (257) when $N > N_0$ since $k + \varsigma - 1 \leq K_1(N)$. We can upper bound the spectral norm of matrix E, i.e., $||E||_2$, by the Frobenius norm of E, i.e,

$$||E||_2^2 = \sum_{m \neq l} \left(\sum_{i=1}^{\varsigma} \alpha_{k+m-1,i}\alpha_{k+l-1,i} \right)^2 \tag{325}$$

$$\leq \varsigma^2 \left(\frac{2(1 + B_5)}{d_2} \right)^2 \tag{326}$$

$$< \chi^2 \frac{4(1 + B_5)^2}{d_2^2} \tag{327}$$

$$\leq \bar{\chi}^2 \frac{4(1 + B_5)^2}{d_2^2} \tag{328}$$

where (326) follows from (316). Hence, we may conclude that

$$||A^{-1}||_2^2 < \left(\frac{(d_2 - 1)(1 - B_5)}{d_2} - \frac{2\bar{\chi}(1 + B_5)}{d_2} \right)^{-1} \tag{329}$$

where the right hand side is a positive number, by the definition of d_2. Next, we evaluate

$||\mathbf{v}||^2$.

$$||\mathbf{v}||^2 = \sum_{i=0}^{\varsigma-1} \left(\mathbf{v}_{k+i}^{(N)^T} \mathbf{b}_{k+\varsigma}^{(N)}\right)^2 \tag{330}$$

$$\leq \sum_{i=0}^{\varsigma-1} \left|\left|\mathbf{v}_{k+i}^{(N)^T}\right|\right|^2 \left|\left|\mathbf{b}_{k+\varsigma}^{(N)}\right|\right|^2 \tag{331}$$

$$\leq \frac{\left|\left|\mathbf{b}_{k+\varsigma}^{(N)}\right|\right|^2}{d_2} \sum_{i=0}^{\varsigma-1} \left|\left|\mathbf{b}_{k+i}^{(N)}\right|\right|^2 \tag{332}$$

$$\leq \frac{\varsigma(1+B_5)}{d_2} \left|\left|\mathbf{b}_{k+\varsigma}^{(N)}\right|\right|^2 \tag{333}$$

$$< \frac{\chi(1+B_5)}{d_2} \left|\left|\mathbf{b}_{k+\varsigma}^{(N)}\right|\right|^2 \tag{334}$$

$$\leq \frac{\bar{\chi}(1+B_5)}{d_2} \left|\left|\mathbf{b}_{k+\varsigma}^{(N)}\right|\right|^2 \tag{335}$$

where (332) follows from (309), and (333) follows from (257) when $N > N_0$ since $k+\varsigma-1 \leq K_1(N)$. Finally, we evaluate $||\mathbf{b}||^2$.

$$||\mathbf{b}||^2 = \sum_{i=0}^{\varsigma-1} \left(\mathbf{b}_{k+i}^{(N)^T} \mathbf{b}_{k+\varsigma}^{(N)}\right)^2 \tag{336}$$

$$\leq \varsigma \left(\frac{4B_3^2(K_1(N)+B_4)^{2\tau} T_0^{1+2\gamma}}{(N-1)^\gamma}\right)^2 \tag{337}$$

$$< \chi \left(\frac{4B_3^2(K_1(N)+B_4)^{2\tau} T_0^{1+2\gamma}}{(N-1)^\gamma}\right)^2 \tag{338}$$

$$\leq \bar{\chi} \left(\frac{4B_3^2(K_1(N)+B_4)^{2\tau} T_0^{1+2\gamma}}{(N-1)^\gamma}\right)^2 \tag{339}$$

where (337) follows from (275) when $N > N_2$.

Following from (321), using (335), (339) and (329), we have

$$\begin{aligned}||\mathbf{u}||^2 &= \left|\left|A^{-1}\right|\right|_2^2 \left(||\mathbf{b}|| + ||\mathbf{v}||\right)^2 && (340)\\ &< \left(\frac{(d_2-1)(1-B_5)}{d_2} - \frac{2\bar{\chi}(1+B_5)}{d_2}\right)^{-1} \\ &\quad \left(\sqrt{\frac{\bar{\chi}(1+B_5)}{d_2}}\left|\left|\mathbf{b}^{(N)}_{k+\varsigma}\right|\right| + \sqrt{\bar{\chi}}\left(\frac{4B_3^2(K_1(N)+B_4)^{2\tau}T_0^{1+2\gamma}}{(N-1)^\gamma}\right)\right)^2 && (341)\\ &\le \left(\frac{(d_2-1)(1-B_5)}{d_2} - \frac{2\bar{\chi}(1+B_5)}{d_2}\right)^{-1} \quad \left(2\sqrt{\frac{\bar{\chi}(1+B_5)}{d_2}}\left|\left|\mathbf{b}^{(N)}_{k+\varsigma}\right|\right|\right)^2 && (342)\\ &= \frac{d_2-1}{d_2}\left|\left|\mathbf{b}^{(N)}_{k+\varsigma}\right|\right|^2 && (343)\end{aligned}$$

where (342) follows when N is large enough, due to the fact that $K_1(N)$ satisfies (207), i.e, there exists an integer N_5, such that when $N > N_5$,

$$\sqrt{\bar{\chi}}\left(\frac{4B_3^2(K_1(N)+B_4)^{2\tau}T_0^{1+2\gamma}}{(N-1)^\gamma}\right) \le \frac{\sqrt{\bar{\chi}(1+B_5)}}{d_2}\sqrt{1-B_5} \qquad (344)$$

and (342) is true, and (343) follows from the definition of d_2 by (286). Hence, when N is large enough, more specifically, when $N > \max(N_0, N_2, N_3, N_4, N_5, N_6)$, we have a contradiction with (305). Therefore, we conclude that there must be at least χ eigenvalues of Σ'_N within distance (301) away from any of the clustered λs, furthermore, from the definition of a cluster in (287), there must be at least χ eigenvalues within distance

$$(2\chi+1)\sqrt{d_2}d_0\frac{(k+\bar{\chi}+B_7')^\tau}{(N-1)^\beta} \le (2\bar{\chi}+1)\sqrt{d_2}d_0\frac{(k+\bar{\chi}+B_7')^\tau}{(N-1)^\beta} \qquad (345)$$

away from all of the clustered λs. We pick χ eigenvalues of Σ'_N which are within distance (345) and arbitrarily pair each clustered λ with one of the eigenvalues. These eigenvalues will not be paired with any other λ because all other clusters of λs are at least distance $2\sqrt{d_2}d_0\frac{\left(k+\bar{\chi}+B_7'\right)^\tau}{(N-1)^\beta}$ apart from this cluster.

Finally, by letting

$$d_1 = (2\bar{\chi}+1)\sqrt{d_2}d_0, \quad B_7 = \bar{\chi} + B_7' \qquad (346)$$

we have the desired results when N is large enough, i.e., $N > \max(N_0, N_1, N_2, N_3, N_4, N_5, N_6)$.

9.9.2 Proof of Lemma 8

In the proof of Lemma 8, we will need results from Lemma 6 and 7. Thus, we will first prove that under the condition of Lemma 8, the results of Lemma 6 and 7 apply. Since

$$\lim_{N\to\infty} \vartheta_U^N = 0 \tag{347}$$

for any $0 < \kappa < 1$, when N is large enough, $\theta' < \vartheta_U^N$ is small enough, which means that the result of Lemma 6 is valid. Now we show that the result of Lemma 7 is also true. Let $K_1(N) = \left(\frac{d}{\vartheta_L^N}\right)^{\frac{1}{x}} + c_u$. Because of

$$\lim_{N\to\infty} \frac{1}{\vartheta_L^N N^{\frac{x\gamma}{2\tau}}} = 0, \quad \lim_{N\to\infty} \frac{1}{\vartheta_L^N N^{\frac{x\beta}{x+1+\tau}}} = 0 \tag{348}$$

we have (207) and (208). Because of (347) and the fact that $\vartheta_L^N \leq \vartheta_U^N$, we have (206).

Hence, for any $0 \leq k \leq \left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor$, result of Lemma 7 applies because

$$k \leq \left\lfloor \left(\frac{d}{\vartheta_L^N}\right)^{\frac{1}{x}} + c_u \right\rfloor \leq K_1(N) \tag{349}$$

and N is large enough.

Now, we will use the result of Lemma 6 and 7 to prove Lemma 8. From the properties of the Karhunen-Loeve expansion, we know that

$$\sum_{k=0}^{\infty} \lambda_k = \int_0^{T_0} K(t,t)dt < \infty \tag{350}$$

Thus, for any constant $0 < \kappa < 1$, we have

$$\sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \lambda_k = \sum_{k=0}^{\infty} \lambda_k - \sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{\infty} \lambda_k \tag{351}$$

$$\geq \int_0^{T_0} K(t,t)dt - \sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{\infty} \lambda_k'' \tag{352}$$

$$\geq \int_0^{T_0} K(t,t)dt - \frac{d^{\frac{1}{x}}}{(x-1)\kappa} \theta'^{1-\frac{1}{x}} \tag{353}$$

where we have used (73) in Lemma 6 to obtain (353).

From the definition of matrix Σ_N, we have

$$\sum_{k=0}^{N-1} \mu_k^{(N)'} = \frac{T_0}{N-1} \operatorname{tr}\left(\Sigma_N\right) = \frac{T_0}{N-1} \sum_{i=0}^{N-1} K\left(\frac{i}{N-1}T_0, \frac{i}{N-1}T_0\right) \tag{354}$$

Thus,

$$\begin{aligned}
\sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}}+c_u \right\rfloor+1}^{N-1} \mu_k^{(N)'} &= \sum_{k=0}^{N-1} \mu_k^{(N)'} - \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}}+c_u \right\rfloor} \mu_k^{(N)'} && (355)\\
&\leq \frac{T_0}{N-1} \sum_{i=0}^{N-1} K\left(\frac{i}{N-1}T_0, \frac{i}{N-1}T_0\right) - \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}}+c_u \right\rfloor} \left(\lambda_k - d_1 \frac{(k+B_7)^{\tau}}{(N-1)^{\beta}}\right) && (356)\\
&\leq \frac{T_0}{N-1} \sum_{i=0}^{N-1} K\left(\frac{i}{N-1}T_0, \frac{i}{N-1}T_0\right) - \int_0^{T_0} K(t,t)dt \\
&\quad + \frac{d^{\frac{1}{x}}}{(x-1)\kappa} \theta'^{1-\frac{1}{x}} + \frac{d_1}{(N-1)^{\beta}} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}}+c_u \right\rfloor} (k+B_7)^{\tau} && (357)\\
&\leq \frac{BT_0^{1+\alpha}2^{\frac{\alpha}{2}}}{(N-1)^{\alpha}} + \frac{T_0K(0,0)}{N-1} + \frac{d^{\frac{1}{x}}}{(x-1)\kappa} \theta'^{1-\frac{1}{x}} + \frac{d_1}{(N-1)^{\beta}} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}}+c_u \right\rfloor+B_7} k^{\tau} && (358)\\
&\leq \frac{BT_0^{1+\alpha}2^{\frac{\alpha}{2}} + T_0K(0,0)}{(N-1)^{\alpha}} + \frac{d^{\frac{1}{x}}}{(x-1)\kappa} \theta'^{1-\frac{1}{x}} \\
&\quad + \frac{d_1}{(\tau+1)(N-1)^{\beta}} \left(\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + B_7\right)^{\tau+1} && (359)\\
&\leq \frac{BT_0^{1+\alpha}2^{\frac{\alpha}{2}} + T_0K(0,0)}{(N-1)^{\alpha}} + \frac{d^{\frac{1}{x}}}{(x-1)\kappa} \theta'^{1-\frac{1}{x}} + \frac{2d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)\theta'^{\frac{\tau+1}{x}}(N-1)^{\beta}} && (360)\\
&\leq \frac{d^{\frac{1}{x}}}{(x-1)\kappa^2} \theta'^{1-\frac{1}{x}} && (361)
\end{aligned}$$

where (356) follows by Lemma 7. We have used (353) to obtain (357), and condition 2 in

Section 3 to obtain (358), (359) follows from the fact that $\alpha \leq 1$ and that

$$\sum_{k=0}^{n} k^{\tau} \leq \int_{0}^{n} y^{\tau} dy = \frac{1}{\tau+1} n^{\tau+1} \tag{362}$$

(360) follows because (347) and when N is large enough, we have

$$c_u + B_7 < \frac{d}{\vartheta_U^N} \leq \frac{d}{\theta'} \tag{363}$$

(361) follows because

$$\lim_{N\to\infty} \frac{1}{\vartheta_L^N N^{\frac{\alpha x}{x-1}}} = 0 \tag{364}$$

and

$$\lim_{N\to\infty} \frac{1}{\vartheta_L^N N^{\frac{\beta x}{1+x+\tau}}} = 0 \Rightarrow \lim_{N\to\infty} \frac{1}{\vartheta_L^N N^{\frac{\beta x}{x+\tau}}} = 0 \tag{365}$$

and when N large enough, i.e., there exists a $N_5(\kappa) > 0$ such that when $N > N_5(\kappa)$, we have

$$\frac{\frac{BT_0^{1+\alpha} 2^{\frac{\alpha}{2}} + T_0 K(0,0)}{(N-1)^{\alpha}}}{\frac{d^{\frac{1}{x}}}{(x-1)} \theta'^{1-\frac{1}{x}}} \leq \frac{\frac{BT_0^{1+\alpha} 2^{\frac{\alpha}{2}} + T_0 K(0,0)}{(N-1)^{\alpha}}}{\frac{d^{\frac{1}{x}}}{(x-1)} \left(\vartheta_L^N\right)^{(1-\frac{1}{x})}} \leq \frac{1}{2}\left(\frac{1}{\kappa^2} - \frac{1}{\kappa}\right) \tag{366}$$

$$\frac{\frac{2d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)\theta'^{\frac{\tau+1}{x}} (N-1)^{\beta}}}{\frac{d^{\frac{1}{x}}}{(x-1)} \theta'^{1-\frac{1}{x}}} \leq \frac{\frac{2d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)\left(\vartheta_L^N\right)^{\frac{\tau+1}{x}} (N-1)^{\beta}}}{\frac{d^{\frac{1}{x}}}{(x-1)} \left(\vartheta_L^N\right)^{1-\frac{1}{x}}} \leq \frac{1}{2}\left(\frac{1}{\kappa^2} - \frac{1}{\kappa}\right) \tag{367}$$

Therefore, for any $0 < \kappa < 1$, (211) holds for $\theta' \in [\vartheta_L^N, \vartheta_U^N]$ when N is large enough.

9.10 Proof of Lemma 4

Since the condition of Lemma 4 is the same as Lemma 8, the results of Lemma 6, 7 and 8 hold. By the same argument as Lemma 6, Lemma 5 holds as well.

We first prove (51). Since ϑ_L^N satisfies

$$\lim_{N\to\infty} \frac{1}{\vartheta_L^N N^{\frac{\beta x}{x+\tau+1}}} = 0 \Rightarrow \lim_{N\to\infty} \frac{1}{\vartheta_L^N N^{x}} = 0 \tag{368}$$

when N is large enough such that

$$\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1 \leq \left\lfloor \left(\frac{d}{\vartheta_L^N}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1 < N - 1 \tag{369}$$

we can provide an upper bound on $R_a^N(\theta')$ by splitting the sum of N variables into two parts,

$$R_a^N(\theta') = \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \frac{1}{2}\log\left(1 + \frac{\mu_k^{(N)'}}{\theta'}\right) + \sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{N-1} \frac{1}{2}\log\left(1 + \frac{\mu_k^{(N)'}}{\theta'}\right) \tag{370}$$

For any $0 < \kappa < 1$, we start with the first term in (370).

$$\begin{aligned}
&\sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \frac{1}{2}\log\left(1 + \frac{\mu_k^{(N)'}}{\theta'}\right) \\
\leq\ &\sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \frac{1}{2}\log\left(1 + \frac{\lambda_k}{\theta'} + d_1\frac{(k+B_7)^\tau}{\theta'(N-1)^\beta}\right) && (371) \\
\leq\ &\sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \frac{1}{2}\log\left(1 + \frac{\lambda_k}{\theta'}\right) + \frac{d_1}{2\theta'(N-1)^\beta}\sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} (k+B_7)^\tau && (372) \\
\leq\ &\sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \frac{1}{2}\log\left(1 + \frac{\lambda_k''}{\theta'}\right) + \frac{d_1}{2\theta'(N-1)^\beta}\sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + B_7} k^\tau && (373) \\
\leq\ &\left(\frac{\log 2 + x}{2\kappa}\right) d^{\frac{1}{x}}\theta'^{-\frac{1}{x}} + \frac{d_1}{2(\tau+1)\theta'(N-1)^\beta}\left(\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} \right\rfloor + c_u + B_7\right)^{\tau+1} && (374) \\
\leq\ &\left(\frac{\log 2 + x}{2\kappa}\right) d^{\frac{1}{x}}\theta'^{-\frac{1}{x}} + \frac{d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)\theta'^{\frac{\tau+1+x}{x}}(N-1)^\beta} && (375) \\
\leq\ &\left(\frac{\log 2 + x}{2\kappa^2}\right) d^{\frac{1}{x}}\theta'^{-\frac{1}{x}} && (376)
\end{aligned}$$

where (371) follows from Lemma 7. (372) follows because the derivative of the function $\frac{1}{2}\log(1+x)$ is bounded by $\frac{1}{2}$ for $x \geq 0$, (373) follows from the definition of the sequence λ_k'' in (11) and the observation in (12), (374) follows because of (74) in Lemma 6, and the observation in (362). (375) follows because of the same reason as (360), and (376) follows because of (365), and when N is large enough, more specifically, there exists an $N_6(\kappa) > 0$

such that when $N > N_6(\kappa)$, we have

$$\frac{\frac{d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)\theta'^{\frac{\tau+1+x}{x}}(N-1)^{\beta}}}{\left(\frac{\log 2+x}{2}\right) d^{\frac{1}{x}} \theta'^{-\frac{1}{x}}} \leq \frac{\frac{d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)\left(\vartheta_L^N\right)^{\frac{\tau+1+x}{x}}(N-1)^{\beta}}}{\left(\frac{\log 2+x}{2}\right) d^{\frac{1}{x}} \left(\vartheta_L^N\right)^{-\frac{1}{x}}} < \left(\frac{1}{\kappa^2} - \frac{1}{\kappa}\right) \tag{377}$$

Now, we will study the second term of (370). Using Jensen's inequality [24], the second term of (370) is bounded by

$$\sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{N-1} \frac{1}{2} \log\left(1 + \frac{\mu_k^{(N)'}}{\theta'}\right) \tag{378}$$

$$\leq \frac{N - \left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor - 1}{2} \log\left(1 + \frac{1}{\theta'} \frac{1}{N - \left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor - 1} \sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{N-1} \mu_k^{(N)'}\right) \tag{379}$$

$$\leq \frac{d^{\frac{1}{x}}}{2(x-1)\kappa^2} \theta'^{-\frac{1}{x}} \tag{380}$$

where in obtaining (380), we have used (211) in Lemma 8 and the fact that $\log(1+x) \leq x$.

We combine the results of (376) and (380) and obtain

$$R_a^N(\theta') \leq \frac{d^{\frac{1}{x}}\left(x^2 - (1-\log 2)x + (1-\log 2)\right)}{2(x-1)\kappa^2} \theta'^{-\frac{1}{x}} \tag{381}$$

Using similar methods, we may also lower bound $R_a^N(\theta')$. We write

$$R_a^N(\theta') = \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} - c_l \right\rfloor} \frac{1}{2} \log\left(1 + \frac{\mu_k^{(N)'}}{\theta'}\right) + \sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} - c_l \right\rfloor + 1}^{N-1} \frac{1}{2} \log\left(1 + \frac{\mu_k^{(N)'}}{\theta'}\right) \tag{382}$$

We start with the first term of (382),

$$\sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} - c_l \right\rfloor} \frac{1}{2}\log\left(1 + \frac{\mu_k^{(N)'}}{\theta'}\right) \geq \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} - c_l \right\rfloor} \frac{1}{2}\log\left(1 + \frac{\lambda_k}{\theta'} - d_1 \frac{(k+B_7)^{\tau}}{\theta'(N-1)^{\beta}}\right) \tag{383}$$

$$\geq \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} - c_l \right\rfloor} \frac{1}{2}\log\left(1 + \frac{\lambda_k}{\theta'}\right) - \frac{d_1}{2\theta'(N-1)^{\beta}} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} - c_l \right\rfloor} (k+B_7)^{\tau} \tag{384}$$

$$\geq \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} - c_l \right\rfloor} \frac{1}{2}\log\left(\frac{\lambda_k'}{\theta'}\right) - \frac{d_1}{2\theta'(N-1)^{\beta}} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} - c_l \right\rfloor + B_7} k^{\tau} \tag{385}$$

$$\geq \frac{\kappa x d^{\frac{1}{x}}}{2}\theta'^{-\frac{1}{x}} - \frac{d_1}{2(\tau+1)\theta'(N-1)^{\beta}} \left(\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} - c_l \right\rfloor + B_7\right)^{\tau+1} \tag{386}$$

$$\geq \frac{\kappa x d^{\frac{1}{x}}}{2}\theta'^{-\frac{1}{x}} - \frac{d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)\theta'^{\frac{\tau+1+x}{x}}(N-1)^{\beta}} \tag{387}$$

$$\geq \frac{\kappa x d^{\frac{1}{x}}}{4}\theta'^{-\frac{1}{x}} \tag{388}$$

where (383) follows when applying the result of Lemma 7. (384) follows because the function $\frac{1}{2}\log(1+x)$ has derivative bounded by $\frac{1}{2}$, when $x \geq 0$. The first term in (386) follows because of (72) in Lemma 5. The second term follows because of (362), (387) follows because of similar reasons as (360), and (388) follows because of (365), and when N is large enough, we have

$$\frac{\frac{d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)\theta'^{\frac{\tau+1+x}{x}}(N-1)^{\beta}}}{\frac{x d^{\frac{1}{x}}}{4}\theta'^{-\frac{1}{x}}} \leq \frac{\frac{d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)\left(\vartheta_L^N\right)^{\frac{\tau+1+x}{x}}(N-1)^{\beta}}}{\frac{x d^{\frac{1}{x}}}{4}\left(\vartheta_L^N\right)^{-\frac{1}{x}}} \leq \frac{1}{8} \tag{389}$$

A lower bound on the second term of (382) is zero. Hence, we can conclude that

$$R_a^N(\theta') \geq \frac{\kappa x d^{\frac{1}{x}}}{4}\theta'^{-\frac{1}{x}} \tag{390}$$

Now we evaluate $D_b^N(\theta')$ for large enough N and $\theta' \in [\vartheta_L^N, \vartheta_U^N]$, and prove (52).

$$D_b^N(\theta') = T_0^{-1} \sum_{k=0}^{N-1} \left(\frac{1}{\theta'} + \frac{1}{\mu_k^{(N)'}} \right)^{-1} \tag{391}$$

$$= T_0^{-1} \sum_{k=0}^{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \left(\frac{1}{\theta'} + \frac{1}{\mu_k^{(N)'}} \right)^{-1} + T_0^{-1} \sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{N-1} \left(\frac{1}{\theta'} + \frac{1}{\mu_k^{(N)'}} \right)^{-1} \tag{392}$$

where (392) follows because of the same reason as (370). The first term of (392) can be bounded as

$$T_0^{-1} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \left(\frac{1}{\theta'} + \frac{1}{\mu_k^{(N)'}} \right)^{-1}$$

$$\le T_0^{-1} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \left(\frac{1}{\theta'} + \frac{1}{\lambda_k + d_1 \frac{(k+B_7)^\tau}{(N-1)^\beta}} \right)^{-1} \tag{393}$$

$$\le T_0^{-1} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \left(\frac{1}{\theta'} + \frac{1}{\lambda_k'' + d_1 \frac{(k+B_7)^\tau}{(N-1)^\beta}} \right)^{-1} \tag{394}$$

$$\le T_0^{-1} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \left(\frac{1}{\theta'} + \frac{1}{\lambda_k''} \right)^{-1} + \frac{d_1}{T_0(N-1)^\beta} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} (k+B_7)^\tau \tag{395}$$

$$\le T_0^{-1} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor} \min\left(\theta', \lambda_k''\right) + \frac{d_1}{T_0(N-1)^\beta} \sum_{k=0}^{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + B_7} k^\tau \tag{396}$$

$$= T_0^{-1} \left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u + 1 \right\rfloor \theta' + \frac{d_1}{(\tau+1)T_0(N-1)^\beta} \left(\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + B_1 \right)^{\tau+1} \tag{397}$$

$$\le \frac{d^{\frac{1}{x}}}{T_0} \theta'^{1-\frac{1}{x}} + \frac{2 d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)T_0(N-1)^\beta \theta'^{\frac{\tau+1}{x}}} + \frac{c_u+1}{T_0}\theta' \tag{398}$$

$$\le \frac{d^{\frac{1}{x}}}{T_0 \kappa} \theta'^{1-\frac{1}{x}} \tag{399}$$

where (393) is true because of Lemma 7. (395) follows because the derivative of the function $\left(\frac{1}{\theta'} + \frac{1}{x}\right)^{-1}$ is bounded by 1, and (396) follows from the fact that for $a, b \ge 0$, $\left(\frac{1}{a} + \frac{1}{b}\right)^{-1} \le$

$\min(a,b)$. (397) follows because of (362) and the fact that when $K = \left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor$,

$$\lambda''_{K+1} \le \theta' \le \lambda''_K \tag{400}$$

(398) follows because of the same reason as (360), and finally (399) follows because (365) and (347) and when N is large enough, i.e., for any $0 < \kappa < 1$, there exists $N_7(\kappa) > 0$ such that when $N > N_7(\kappa)$, we have

$$\frac{\frac{2d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)T_0(N-1)^{\beta}\theta'^{\frac{\tau+1}{x}}}}{\frac{d^{\frac{1}{x}}}{T_0}\theta'^{1-\frac{1}{x}}} \le \frac{\frac{2d_1 d^{\frac{\tau+1}{x}}}{(\tau+1)T_0(N-1)^{\beta}\left(\vartheta_L^N\right)^{\frac{\tau+1}{x}}}}{\frac{d^{\frac{1}{x}}}{T_0}\left(\vartheta_L^N\right)^{1-\frac{1}{x}}} \le \frac{1}{2}\left(\frac{1}{\kappa} - 1\right) \tag{401}$$

$$\frac{\frac{c_u+1}{T_0}\theta'}{\frac{d^{\frac{1}{x}}}{T_0}\theta'^{1-\frac{1}{x}}} \le \frac{\frac{c_u+1}{T_0}\vartheta_U^N}{\frac{d^{\frac{1}{x}}}{T_0}\left(\vartheta_U^N\right)^{1-\frac{1}{x}}} \le \frac{1}{2}\left(\frac{1}{\kappa} - 1\right) \tag{402}$$

The second term of (392) can be bounded by using Jensen's inequality,

$$T_0^{-1} \sum_{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{N-1} \left(\frac{1}{\theta'} + \frac{1}{\mu_k^{(N)'}}\right)^{-1}$$

$$\le \frac{N - \left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor - 1}{T_0} \left(\frac{1}{\theta'} + \frac{1}{\frac{1}{N - \left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor - 1} \sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{N-1} \mu_k^{(N)'}}\right)^{-1} \tag{403}$$

$$\le \frac{N}{T_0}\left(\frac{1}{\theta'} + \frac{1}{\frac{1}{\kappa N}\sum_{k=\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}^{N-1} \mu_k^{(N)'}}\right)^{-1} \tag{404}$$

$$\le \frac{N}{T_0}\min\left(\theta', \frac{d^{\frac{1}{x}}}{(x-1)\kappa^3}\frac{\theta'^{1-\frac{1}{x}}}{N}\right) \tag{405}$$

$$\le \frac{d^{\frac{1}{x}}}{(x-1)T_0\kappa^3}\theta'^{1-\frac{1}{x}} \tag{406}$$

where (404) follows because (368) and when N is large enough, i.e., there exists an $N_8(\kappa) > 0$, such that when $N > N_8(\kappa)$, we have

$$\frac{\left\lfloor \left(\frac{d}{\theta'}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}{N} \le \frac{\left\lfloor \left(\frac{d}{\vartheta_L^N}\right)^{\frac{1}{x}} + c_u \right\rfloor + 1}{N} \le 1 - \kappa \tag{407}$$

(405) follows from (211) in Lemma 8 and (406) follows because of (368) and when N is large

enough, we have

$$\frac{\frac{d^{\frac{1}{x}}}{(x-1)\kappa^3}\frac{\theta'^{1-\frac{1}{x}}}{N}}{\theta'} \leq \frac{\frac{d^{\frac{1}{x}}}{(x-1)\kappa^3}\frac{\left(\vartheta_L^N\right)^{1-\frac{1}{x}}}{N}}{\left(\vartheta_L^N\right)} \leq 1 \tag{408}$$

Thus, combining (399) and (406), we have

$$D_b^N(\theta') \leq \frac{d^{\frac{1}{x}}\left(1+\kappa^2(x-1)\right)}{\kappa^3(x-1)T_0}\theta'^{1-\frac{1}{x}} \tag{409}$$

Therefore, for any $0 < \kappa < 1$, (51) and (52) are true for $\theta' \in [\vartheta_L^N, \vartheta_U^N]$ when N is large enough.

9.11 Proof of Theorem 5

Note that (51) implies that

$$\frac{\kappa^x x^x d}{4^x R^x} \leq \theta_a^N(R) \leq \left(\frac{d^{\frac{1}{x}}\left(x^2-(1-\log 2)x+(1-\log 2)\right)}{2(x-1)\kappa^2}\right)^x R^{-x} \tag{410}$$

for large enough N and R in the interval of

$$\left[\frac{d^{\frac{1}{x}}\left(x^2-(1-\log 2)x+(1-\log 2)\right)}{2(x-1)\kappa^2}\left(\vartheta_U^N\right)^{-\frac{1}{x}}, \frac{\kappa x d^{\frac{1}{x}}}{4}\left(\vartheta_L^N\right)^{-\frac{1}{x}}\right] \tag{411}$$

From the definition of $D_a(R)$ in (46), we have

$$D_a(R) = D_a^N(\theta_a^N(R)) \tag{412}$$

$$\leq 2A^{(N)} + B^{(N)} + D_b^N(\theta_a^N(R)) \tag{413}$$

$$\leq 2A^{(N)} + B^{(N)} + \frac{d^{\frac{1}{x}}\left(1+\kappa^2(x-1)\right)}{\kappa^3(x-1)T_0}\left(\theta_a^N(R)\right)^{1-\frac{1}{x}} \tag{414}$$

$$\leq O\left(N^{-\alpha}\right) + O\left(N^{1/2-\alpha}\right) + \frac{d(1+\kappa^2(x-1))\left(x^2-(1-\log 2)x+(1-\log 2)\right)^{x-1}}{T_0\kappa^{2x+1}2^{x-1}(x-1)^x}R^{1-x} \tag{415}$$

where (413) follows from (39), (414) follows because of (52), (415) follows from (48), (49), (410) and the fact that R in (55) implies that R is in (411), and when R is in (411), $\theta_a^N(R)$ is in $[\vartheta_L^N, \vartheta_U^N]$. When R is in (55), we have that the third term in (415) is much larger than the sum of the first and second terms when N is large enough due to the fact that

$$\lim_{N\to\infty} \frac{1}{\vartheta_{LL}^N N^{\frac{(\alpha-1/2)x}{x-1}}} = 0 \Rightarrow \lim_{N\to\infty} \frac{1}{\vartheta_{LL}^N N^{\frac{\alpha x}{x-1}}} = 0 \tag{416}$$

i.e., there exists an $N_9(\kappa) > 0$ such that when $N > N_9(\kappa)$, we have

$$\begin{aligned}
&\frac{O\left(N^{-\alpha}\right) + O\left(N^{1/2-\alpha}\right)}{\frac{d(1+\kappa^2(x-1))(x^2-(1-\log 2)x+(1-\log 2))^{x-1}}{T_0 2^{x-1}(x-1)^x} R^{1-x}} \\
&\leq \frac{O\left(N^{-\alpha}\right) + O\left(N^{1/2-\alpha}\right)}{\frac{d(1+\kappa^2(x-1))(x^2-(1-\log 2)x+(1-\log 2))^{x-1}}{T_0 2^{x-1}(x-1)^x} \left(\frac{xd^{\frac{1}{x}}}{8} \left(\vartheta_{LL}^N\right)^{-\frac{1}{x}}\right)^{1-x}} \qquad (417) \\
&\leq \frac{1}{\kappa^{2x+2}} - \frac{1}{\kappa^{2x+1}} \qquad (418)
\end{aligned}$$

Therefore, for $0 < \kappa < 1$, (54) is true for R in the interval of (55) when N is large enough.

9.12 Proof of Theorem 6

Pick the sequences ϑ_{LL}^N and ϑ_U^N as

$$\vartheta_{LL}^N = \left(\frac{\nu}{\frac{xd^{\frac{1}{x}}}{8}} \log NP(N)\right)^{-x}, \quad \vartheta_U^N = \left(\frac{\nu}{\frac{d^{\frac{1}{x}}(x^2-(1-\log 2)x+(1-\log 2))}{2(x-1)\kappa^2}} \log NP(N)\right)^{-x/2} \tag{419}$$

Then, because $P(N)$ satisfies (43) and (56), ϑ_{LL}^N satisfies (53) and ϑ_U^N satisfies (50). According to (44), we have the achievable rate in the interval of (55), and thus, when N is large enough, Theorem 5 applies. Hence, an upper bound on the minimum achievable expected distortion, or equivalently, the achievable rate in the separation-based scheme is

$$\begin{aligned}
D_u^N &= D_a\left(C_a^N\right) \qquad (420) \\
&\leq \frac{d(1+\kappa^2(x-1))\left(x^2-(1-\log 2)x+(1-\log 2)\right)^{x-1}}{T_0 \kappa^{3x+1} 2^{x-1}(x-1)^x \nu^{x-1}} \left(\frac{1}{\log(NP(N))}\right)^{x-1} \qquad (421)
\end{aligned}$$

Therefore, when $P(N)$ satisfies (43) and (56), for any $0 < \kappa < 1$, (58) holds when N is large enough.
